2. The fan will not burn out. All FA-7s were 120 Volts and the PSUs are wired such that the fan always gets 120 Volts, no matter if 240 or 120 is set as primary voltage. The PS-75 is a bit weak for the TR7, though. Fine for SSB maybe but in CW you should not use full output power.

Good luck and let us know if there are more issues.

One more note:

Do the usual board-reseating process before you start any trouble-shooting. Pull out ALL boards, the ones under the rear cage, the DR-7 and the ones below the DR-7. You *may* add some Deoxit to all the contacts before you put them back. This may also resolve your band-switching problem. Sounds like a bit in the band information is missing in the DR-7.

A calibrator is in all TR7s.

I had a PTO that was kind of stiff (not stuck). The problem was some old grease and dirt in the brass area. If you dismantle the whole thing and clean it you should be able to get it working again.

20484. T4XC plate current too high?

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-04-29 00:48:25 UTC
From: <rochep@...>
Topic: 20484 Message: 20484

I just checked the bias voltage on my T4XC, everything checks out (the 3.3 ohm shunt resistor is still good) and set the bias for 70 mA on the dial. (I have been using it probably closer to 50 mA because of dial calibration). I also adjusted the RF and injector trimmers on each band (they were close). But I notice I can REALLY get RF out of this transmitter, MUCH more than I thought possible?

on 80 CW into a dummy load (measuring plate current from the T4XB meter and power OUTPUT with two different watt meters):

With plate current of 0.50 amps (325 watts input) I measure 150 watts output (46% efficient).

With plate current of 0.52 amps (338 watts input) I measure 180 watts output (53% efficient)

Max output is over 200 watts out!! The plate current is WELL over 0.5 amps! (for just a second, just to see what I could get out).

I believe the efficiency values and I believe my wattmeters. I usually go for only 100 watts output, but are these numbers I read in the right ballpark? I thought the max these tubes could do was 200 watts INPUT?

This is a T4XB isn't it, not a TR-4? The power levels do
not sound right. Around 150 watts is high for 80 meters.
Are you sure the final is not oscillating? Do the plates
show any color? I am sure Garry will have something to say
about this.

Mark:

If you have a failed part in there, you will likely have to remove the PTO from the chassis anyways to get at it and replace it. Most PTO gearing needs a good cleaning by now and to do that properly the PTO needs to come out. It’s not a difficult task on the R-4A – three screws and three wires. Although you do have to remove the front panel to get it out. Some may disagree with that but I have found that removing the front panel, and more importantly, the clear dial window, makes it a lot easier! It will all need cleaning anyways. I do that with ALL my Drake 4-line acquisitions.

FWIW, I just tried my T4XB on 80 meters. I use an
external Motorola dummy load that measures 50 ohms on a
General Radio RF bridge. The watt meter is the one in my
MFJ antenna tuner. I've checked its calibration on the dummy
load against a couple of accurate RF voltmeters (General
Radio 1800A on a GR coaxial T). My maximum power in CW with
carefull tuning is a pointer's width above 160 Watts.

Indicated current is 380 ma. Now, the meter reads cathode current which is a combination of plate and screen grid current. I don't know how much current the screens draw, perhaps a few ma, plus I did not measure the plate voltage but assume it was about 650 volts from previous measurements under load. That comes out to around 247 Watts input. The efficiency assuming this is an accurate number (its probably reasonably close) the efficiency is about 65%, about what one would expect from a Class-AB amplifier running at maximum output. I have tested in the past and find I get about the same output on 40 meters but less on other bands including 160. Since there is no ALC when in CW this is probably the absolute maximum this particular transmitter is cabable of. The tubes are in reasonable condition and I do get fairly high output on 10 meters. If you meaure in TUNE you will be limited by the ALC to about 130 Watts, less on bands where the amplifier won't make it. The high output would make me suspicious of parasitics. While this is much less likely on a low band than at, say, 10 meters, its still possible. Its also possible that there is an unusual amount of drive. What does the rig do in TUNE?

Subject: Re: [DrakeRadio] T4XC plate current too high?

Another measurment. I decided to try 10 meters. Set up
as before. Max out in CW 140 Watts, curent indicated 360 ma.
indicated plate input 234 watts, assuming Ep = 650 volts.
Efficiency approximately 60%. In TUNE maximum power out is
about 120 Watts. This is pretty good for a T4.
I checked to see that the plate current dip co-incided
with output power peak. Plates show no color.

Paul -

Yeah, that's too high. With new PA (6JB6) tubes, you can get about 140W output in TUNE MODE on
the low bands. This is ALC limited, and typically occurs at about 11 o'clock on the GAIN control. If you switch to CW, the ALC is disabled plus the current limiting on the PA screens
is removed, and you can get 150W max into a 50 ohm, resistive load. 160M falls off a bit due to
Pi-Net limitations.

If you are getting 200W output, something is wrong. The TR-4(C) will put out about 200W max with THREE (3) PA tubes.

Have you checked neutralization of the PA?? You may have some sort of parasitic oscillation in
the PA.

As for your input power, I'd cross check the plate meter with a known good meter. These are very inexpensive meters, (<$1 in production quantities,) and are not known for their linearity... Which is why we calibrate them at 70 mA, as that is the current that matters.

Typical efficiency is 50 - 55% based on Cathode current x Plate voltage, a little less on the
top two bands. The original power supply is pretty consistent at 650 VDC at full load and 120
VAC primary power.

By the way, the 'Revised Tune-up' from Drake specifies 340 mA MAX current on 160, 80, 40 and
20M, to comply with the revised FCC regulations regarding 'Purity of Emissions'. 15 and 10M are
tuned for maximum output. I doubt if any of them come close to meeting TODAY'S 'Purity of Emissions' regulation, but thankfully they are 'grandfathered in' by FCC.

To be honest, I don't really believe my plate current IS that high, and I was surprised I could get 200 watts!!! Can I simply disconnect the T4XC meter and use my DMM to measure the plate current? I would believe that.

On TUNE I am limited to about 130 watts, these high readings were on CW. I never run the rig this high, just wonderin' if something is wrong.

I checked for "neutralization" insofar as the plate DIP is at maximum output (on all bands). Done for tonight, I'll keep reading.

Paul -

Couple of ways.

1. You know the value of your 3.3 ohm meter shunt resistor. Measure the voltage across the meter and the series calibration resistor and calculate. All topside, and no soldering!

2. Disconnect the Cathode lead coming through the bypass cap on the PA shield wall under the
chassis and put your DMM in series with it. Rig upside down and soldering involved.

From: David Nichols
Topic: 20496 Message: 20496

I need a couple of crystals for the alignment of my R4-B.
I need to get on WWV at 15 MHz or 10 MHz, there are four xtals that will do the job.
25.6 and 26.1 for 15MHz and 20.6 or 21.1, Either will do for me.
The instructions also call for a 12.6 crystal so if anyone has these and dont mind parting with them please let me know how much you will need for the shipping and crystals.
Im good in the book if you need a zip.

FWIW all the WARC band crystals are available from
International Crystal. However, if you just want to set the
calibrator you can use any radio you have that will receive
WWV. The calibrator is connected at the antenna input so you
can just hang a loop from that to the WWV receiver and hear
the calibrator. The 12.6 mhz crystal is necessary if you
want to align `160 meters but is not needed for anything
else. If you want to use 160 you will need the crystal
anyway.
I bought a full set of crystals except one (that came
from someone else) for my R4B to cover the WARC bands and
all of 10 meters. The `10 mhz WWV crytal also covers 30
meters.

There are cheaper sources of crystals but ICM has all
the Drake specs and their crystals are newly manuactured and
excellent. I've also bought crystals from them for Collins
gear.

20498. TR-4CW band switch

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-04-29 05:21:30 UTC
From: David Nichols
Topic: 20498 Message: 20498

Ok, I am pretty happy with the rig now. It really helps warm the shack up this time of year. But, I have noticed a problem with the band switch at the 40 meters position.

These are my observations, first of all it works fine on 40 if I set it the right way and we all know I shouldnt really have to monkey with it.
If I go to 40 from 80 the switch doesnt usually make up. If I go to 40 from 20 it seems to work every time. I have checked the wafers and cleaned them all. The cleaning was a job, when I got the rig each wafer had some kind of grease on it. I have never seen this done before and I suppose I am lucky it is working at all. Anyway, I used a lot of deox and even cleaned the tarnish and grease off. Then I used the deox gold on all wafers. So, I can hear the difference in the receive on 40 now that I have learned it has the problem. It really doesnt have much of a receive unless I take it from 20 to 40.
The big question??? Which wafer is most likely the one I need to fix? I would rather ask this than spend a day trying to figure it out with trial and mostly error.

20499. L4B - low output with new tubes.

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-04-29 06:16:00 UTC
From: <engstrommike@...>
Topic: 20499 Message: 20499

I purchase an L4B with low output on all bands thinking it was the tubes. Replaced the tubes and the same exact problem. It takes only 20 watts of drive to generate 280 milliamps of grid current and about 350 mils plate current. Tune and load positions are normal into a 50 ohm resistive load. It is acting as if there is very low high voltage but high voltage is normal at around 2.5 KV underload. All the RF chokes look normal, no burn marks. Continuity is excellent on RFC4 (to the 3-500's anode). Single side band audio quality is normal at the 400 watts. Its like it is not able to load the antenna... not able to transfer the power it is capable of generating. Anyone out there have any ideas? Thanks

Have you tried all bands? Mine had low output and acted funny on two bands, and was found to be contact fingers that had lost their temper on the band switch resulting in poor, or no contact. Would have taken forever to find had I not seen a small arc.

Let us know what you find.

Yes, the output is low (400 watts) on 80, 40, 20, 15 and 10. The band switch looks in good shape, plenty of tension on the fingers and contacts. Thank you.

Hi Mike,

I wonder if you have an open circuit on the Heater Line to one of the Tubes,

Therefore only one tube is working.

Maybe a problem with a Tube Socket, or a Dry joint.

I had a similar issue on another make of Amp.

The knob is probably slipping on the shaft. It uses a spacer between the knob and the shaft, but before you tighten it too much, consider disassembling it, cleaning out the dried old grease and regreasing it. Use general purpose grease on the areas where you see the old grease, after you clean out the old stuff with mineral spirits. You may have to unsolder two places at the back of the box to get the back cover off.

20505. TR7: replacing 2nd IF/Audio Board ?

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-04-29 11:41:45 UTC
From: <damico@...>
Topic: 20505 Message: 20505

Hello group,
I have a tough question for the knowledgeable gurus: I have a TR7 that mounts the 1st version of the 2nd IF / Audio Board (the one with the diode detector). I have also at hand the 2nd version of the board, the one that mounts the MC1496.
Now the question is: are they perfectly interchangeable ? Can I just "plug-in" board version 2 in place of the version 1 ?
Thanks for any advice on this....

When Drake changed to the late 2nd IF/ Audio
board they made a small change to the PBT/REF
board, They removed R1058 (220 ohm) and then
removed R1060 (68 ohm) and put R1060 where R1058
was. This was to increase the BFO signal into the
MC1496 product detector. On the PBT/REF board you
should see 2 68 ohm resistors with an empty spot
between them. Even in the latest service manual the change was not documented.

Hi Michele

I did it on one of my TR7's some years ago, and I thought the Audio Response was much "smoother".

So for the small amount of work required, I would say Yes.

Hello Keith,
I have good heater voltage to both tubes. They both light up as you would expect. When I put those tubes in a different amplifier it will do 1500 watts easy. I think the answer lies in the fact that the amplifier develops 280ma of grid current with only 20 watts of drive, and only 350ma of plate current. The thing is I don't know that much about amplifiers, but I'm wondering if maybe 1 or both the doorknob capacitors on the anodes might be bad?
Thank you.

Michele

The second version of the 2nd IF board is functionally equivalent to the first version. Either version can be placed in any TR7 without requiring modifications.

If the second version board is an unknown quantity, checking function and alignment after installation might be useful. There are modifications offered to the 2nd IF board that reduce key clicks on CW and improve the frequency response of the audio output stage. I have tried the audio output modifications and found improvement. Have not checked into the CW modifications yet.

David -

Keep moving..... The Calibrator can't be moved far enough off frequency to matter for alignment. If you haven't adjusted it, it's almost certainly within a few Hz at worst.

If you have a local broadcast station on a 25 or 50 kHz interval, you can connect a wire to the
R-4B antenna lead and bring the other end near the BC radio antenna.

The 12.6 MHz crystal is only used to align the 160M band, and has no effect on other bands. You
only need it if you want to operate on 160M, and can be added at any time.

Hi Mike,

The Grid Current is awfully high, If you increase the Loading, Does that reduce the Grid Current, And increase the Anode Current

As it should?

Also is the Fault there on all bands?

If by increasing the loading, it decreases the grid and increases the anode current it can indicate that :-

A, The Pi Tank is only “seeing “ one Tube, And the Wrong setting you are seeing is because the Impedance with 1 tube is different,

So make sure the Grid Circuits to Earth are both ok.

B You may have a Faulty Band Switch, or Capacitor in the PI Tank , But this would show up if you changed Bands.

Hopefully you will find the fault, and some others will chip in with advice.

BUT DO BE VERY CAREFUL, THERE ARE DANGEROUS VOLTAGES THERE!!!

Subject: RE: [DrakeRadio] L4B - low output with new tubes.

Hello Keith,
I have good heater voltage to both tubes. They both light up as you would expect. When I put those tubes in a different amplifier it will do 1500 watts easy. I think the answer lies in the fact that the amplifier develops 280ma of grid current with only 20 watts of drive, and only 350ma of plate current. The thing is I don't know that much about amplifiers, but I'm wondering if maybe 1 or both the doorknob capacitors on the anodes might be bad?
Thank you.

Ok Garey, I havent touched it yet. I dont have the items they call for in the instructions so I wont get to it until I have what I need to do the job. I couldnt begin to say what someone else has done so I like to know where Im at with my rigs.
Im about 70 miles from Spokane and there is one radio station up here about 18 miles north of me. I cant pick it up worth a darn and I really dont care because I dont care for their format. hi hi
I had thought about teaming the receiver up with the TR-4CW instead of a vfo and for that I dont need 160 for sure. But, If I get it done, maybe Ill like the way it sounds.

David -

Keep moving..... The Calibrator can't be moved far enough off frequency to matter for alignment. If you haven't adjusted it, it's almost certainly within a few Hz at worst.

If you have a local broadcast station on a 25 or 50 kHz interval, you can connect a wire to the
R-4B antenna lead and bring the other end near the BC radio antenna.

The 12.6 MHz crystal is only used to align the 160M band, and has no effect on other bands. You
only need it if you want to operate on 160M, and can be added at any time.

Install only one tube in the amp and attempt to load it up and see if the Ip and Ig readings are what you have seen with two tubes. Shut the amp down and verity the HV has dissipated from the amp, move the tube to the other socket and repeat. This will prove or disprove that one the SOCKETS electrical components has failed. If one socket doesn't work then you know where to start your search.

Joe

Thanks for that info on the BFO injection change on the PBT board. I wasn't aware of this change or recall having this detail discussed on the sites that discuss the product detector change of the 2nd IF board. I have TR7's, one with early and another with late 2nd IF boards. The TR7 with the later version of 2nd IF board does sound better to me.

I've read where this change to the 2nd IF board was only a cost reduction and did not yield improved audio.

I have TR7 s/n 10XX and 91XX. I will try a swap of the later PBT and 2nd IF boards into the early TR7 and see if there is an obvious change in recovered audio.

I did the audio stage mods to the early version of the 2nd IF board and did perceive and improvement.

Subject: Re: [DrakeRadio] TR7: replacing 2nd IF/Audio Board ?

Michele

The second version of the 2nd IF board is functionally equivalent to the first version. Either version can be placed in any TR7 without requiring modifications.

If the second version board is an unknown quantity, checking function and alignment after installation might be useful. There are modifications offered to the 2nd IF board that reduce key clicks on CW and improve the frequency response of the audio output stage. I have tried the audio output modifications and found improvement. Have not checked into the CW modifications yet.

Subject: [DrakeRadio] TR7: replacing 2nd IF/Audio Board ?

Hello group,

I have a tough question for the knowledgeable gurus: I have a TR7 that mounts the 1st version of the 2nd IF / Audio Board (the one with the diode detector). I have also at hand the 2nd version of the board, the one that mounts the MC1496.

Now the question is: are they perfectly interchangeable ? Can I just "plug-in" board version 2 in place of the version 1 ?

Thanks for any advice on this....

73,

Michele IZ2EAS

Keith,

A number of things can be examined. Something is definately wrong. First, 280 ma of grid current is excessive and should be avoided. Something in the 200-220 range is best per the Eimac spec sheet. With that low amount of drive (20 watts) it is surprising you are getting that much grid current, and the plate current is on the low side. Things I would check are...

Plate blocking capacitors.
RF safety choke across the output lead.
Relay contacts.
Coax connectors.
Calibration of grid current meter circuit.
Calibration of HV meter circuit.
Grid grounding RF chokes on each tube.
Grid bypass ceramic capacitors on each tube.

Please keep the group informed of your progress and be careful around that High Voltage!

73,

Evan

Check your output relay. I've seen similar (albeit with NO output as I had completely melted the contacts!) - mucho grid current, because the power's got to go somewhere...

Topic: 20499 Message: 20521

Hello Keith, At 280ma of grid current, which is around the maximum rated for two tubes as I understand, it should be pulling approximately 800ma plate current. But both tubes are only pulling 300ma plate current. if that's too much grid currant I'll turn the drive down to 10 watts and grid current around 220ma. The loading capacitor is nearly fully CounterClockwise - at maximum capacity. Increasing the load capacitor (turning it ClockWise) does drop the grid current and increase plate current slightly, but there is no additional RF output... it actually drops. Further, there's no dipping of the plate after turning the load capacitor CW. The symptoms are the same on all bands. Thank you for your thoughts Keith. There is more to check.

This morning I looked at my radio on 40 and 80 into dummy load:

40 meters TUNE 100 watts output reads 0.32 Amps on T4XC meter (LOAD control about 4). This is about 53% efficient, seems OK, right?

80 meters TUNE 100 watts output reads 0.45 amps on T4XC meter!!!! And the LOAD control is FULLY MAXED. I just "re-aligned" this TX, maybe my "alignment" was a problem?

I'm looking for the VFO tuning knob and skirt for a TR 4 or R4 B.
If anyone has a knob and skirt for sale, please reply off list to:
wa4bhk@.... Thanks

20532. Re: [DrakeRadio] WTB Knob and Skirt for TR 4 or R4 B

These do show up on eBay once in a while. I bought a NOS knob a couple of months ago that truly is NOS - and looks wicked awesome on my R-4B!

Steve Wedge, W1ES/4

There is a guy selling brand new ones. He's on there all the time. I don't remember his handle though.

I did as you suggested Doug and there is no difference between the two sockets. I think whatever the problem is is after the anodes. Seems all good from the sockets back.

I would like to thank everyone else that has contributed information. This is a most interesting problem. I've always heard that door knob capacitors explode when they go bad, these look good and appear perfectly normal. I'll get a couple and swap them out in addition to all the other suggestions that have been offered. Thank you all very much.
There's two door knob caps... .001's at 5KV
I will report back.

Output relay. You circulate all the current in the tank and nothing is getting out.

Thank you Steve. Checked and cleaned the contacts on the TR relay. They're good. My power meter is external to the L4B so I know the relay is transferring what small amount of power there is to the SO239.

David -

That's a 'pickoff' for a panadaptor, I scope tuned to 5.465 MHz. Something like a Heath HO-13
or similar. It displays a portion of the band, at least that seen by the roofing filter or about 8 kHz wide. Modern transceivers have them now, display is a line along the bottom, with
little pips of varying height, depending upon strength, for any signals in that bandwidth. Some
have modified Software Defined Receiver kits to tune them to that frequency. Look up 'panadaptor' on Google and you'll get plenty of discussion.

You are correct, it doesn't hurt anything, as long as the alignment has been touched up to compensate for the loading.

Thanks Garey,

Confirmed. Its clean, smooth turning and free of dust.

At this point I'm thinking coupling to the tank circuit. All that potential energy... just can't get there... I'm not sure where to get door knob caps. First I need to dig in some old boxes.

My 80M antenna is a dummy load. I re-aligned 3.5 MHz band, but I STILL measure about 150 watts out on 80. I think my wattmeter was wrong on the 1.5 KW setting, what I was reading as 200 watts was probably closer to 150 watts.

OK. Well the measurements you have are exactly what you would see if the LOAD capacitor was stuck at maximum capacitance. Increasing the LOAD control reduces the Grid current as the PLATE
current increases. Is it the same on more than one band?? Is the PLATE dip very sharp??

What does the L-4B Wattmeter show, Forward or Reflected?? Are all four stators of the LOAD cap
tied together and to the 700 pF 'extra' cap on 80M?

I guess an open Plate Blocking cap could present that way, I've never seen one go. It can't be
a component 'shorting' the output as you have plenty of power to fry anything across the output. Are you using a dummy load? Or a known 'matched' antenna?

Surplus Sales of Nebraska has a nice selection of doorknob caps. Also Max-Gain Systems of Marietta, GA.

OK, 150W is much more believeable, at least in CW MODE. If you're seeing that much in TUNE, I'd
wonder if the ALC may not be working? Does the output flatten out about 11 o'clock on the GAIN
control? V1??

20546. CALIBRATOR TONE ON 40 METERS MISSING

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-04-30 02:13:23 UTC
From: David Nichols
Topic: 20546 Message: 20546

Ok, I re-cleaned and inspected the band switch on my TR-4CW today. I seem to have 40 meters working now no matter which way I approach it. It didnt want to work if I turned up from the 80 meter position. However, now I cant get the calibrator signal to come in. The calibrator is working, it comes in fine on all the other bands. Playing with the band switch knob if I approach the 40 meter position from 20 meters and dont let the switch land in the indent I get the calibrator signal. Its a good thing I have spare cabinet screws, it appears Im going to wear these out. Now I thought the calibrator signal came in on the wire that is threaded through the whole in the wafer. How can I get it off of the indent position?

20549. Re: [DrakeRadio] Re: T4XC plate current too high?

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-04-30 04:26:06 UTC
From: <rochep@...>
Topic: 20484 Message: 20549

OK, I THINK part of my problem is in NEUTRALIZATION and another part is ERROR in how to tune this T4XC up!!

I thought that BASICALLY my dip in plate current went well with the increase in output. But I did not realize that close is not close enough!! For example, when I tune for a complete plate DIP at 0.27 amps this does NOT correspond to maximum output power; max power comes a TAD different on the PLATE dial, but at max OUTPUT the plate current reads 0.42 amps!!! I have been using my WATT meter to tune for maximum output.

For example, on 15 CW in TUNE if I SIMPLY go for maximum OUTPUT I get 130 watts out with 0.46 A (on my T4XC meter), or 42% efficiency. But if I instead tune for the DIP in plate current at max output I get 110 watts out at 0.34A, or 50% efficiency. Minimum plate current is clearly the way to go, but since I am not neutralized I am sending my current HIGHER than it has to be, I am off resonance and screwing everything up.

Also, I was tuning back and forth and back and for the MAX output. If I simply follow the directions n TUNE:
1. keep LOAD at 0 and peak RF TUNE
2. set GAIN to 12 o'clock and then DIP plate
3. increase LOAD until I get no more output power
4. Re-dip plate a last time

NOW things seem normal into dummy load:
on 80 CW 140 watts out at 0.42A (52% efficiency)
on 40 CW 140 watts out at 0.39A (55% efficiency)
on 20 CW 150 watts out at 0.43A (53% efficiency)
on 15 CW 100 watts out at 0.34A (45% efficiency)
on 10 CW 70 watts out at 0.32A (35% efficiency)

This is WITHOUT rocking back and forth increasing gain, re-dip PLATE, re-peak LOAD, etc...

I think my high readings of plate current are a neutralization problem, I will fix this<

QUESTION: Why is neutralization done on the 28.5 MHz band? I rarely use that band, I usually use 40 or 15 meters. Is it OK to do neutralization on 40 or 20, or is there something special about doing it on 10 meters?

Am I barking up the right tree?

paul

Hello Garey,

Rotating the Load has little effect on the grid current. Rotating the load Clock Wise increases plate current and diminishes power output. The increased plate current responds to a very shallow re dipping of the plate with diminished power out. Power output is greatest (abt 400 watts) with load at full CCW position which is max capacitance. (That's not right!) The plate current dip is rather sharp with the load control full CCW . I am using a Heath Kit cantenna oil filled dummy load. Results are the same on all bands.

L4B watt meter shows about 400 Watts forward and just a few watts reflected. The load capacitor is all tied together and there's an extra cap in there for 80 meters. Its functions fine mechanically.

From: Steve Wedge
Topic: 20553 Message: 20553

Going to have an SPR-4 ready shortly. It's working fine; I did a few minor tweaks to it and replaced the antenna connector with a new, correct RCA jack (the old one was loose and chewed up inside). Top bank is full of xtals, which is what came from the factory. Cosmetically, there are a couple of round scratch marks on the front panel from knobs that were too close (we've all seen this), a few small scratches in the covers. The covers appear to be of the painted variety instead of the plastic-like covering that some of them had. Still has the same type of surface (crackle?).

Unmodified and the power supply board has no signs of excessive heat dissipation like some of them have.

$350. Photos by this evening.

> Ok, I re-cleaned and inspected the band switch on my TR-4CW today. I seem to have 40 meters working now no matter which way I approach it. It didnt want to work if I turned up from the 80 meter position. However, now I cant get the calibrator signal to come in. The calibrator is working, it comes in fine on all the other bands. Playing with the band switch knob if I approach the 40 meter position from 20 meters and dont let the switch land in the indent I get the calibrator signal. Its a good thing I have spare cabinet screws, it appears Im going to wear these out. Now I thought the calibrator signal came in on the wire that is threaded through the whole in the wafer. How can I get it off of the indent position?

Measure voltages on V4, V11 and V17. The S-Meter is in a bridge circuit that compares the current drawn by V17 with that drawn by V4 and V11. With no input signal the bridge is 'balanced' by adjustment of R70. When the AVC, which goes more negative with increasing signal
strength reduces the current drawn by V11 and unbalances the bridge. This unbalance causes the
meter to read upscale an amount set by R187.

David/Carl:

Actually, when using the TC-2 and TC-6 tx converters, the HF RECEIVE line from the T-4XB is usually routed through a band selector switch in the CC-1 receive converter console, which is then routed directly back to the RX ANT input on the R-4B when HF is selected. There was no mod required for the R-4 receiver series.

It’s the TX line for the transmit converters that uses a small value cap (I’ve used a gimmick in the past) to pick off a bit of RF out of the PA grid compartment.

The VHF mod also required a break in the PA screen voltage line which was run out to two spare RCA connectors you mounted in existing holes on the back of the T-4X. Turning on either the TC-2 or TC-6 disabled the PA. If you run across a T-4X , TR-4 series with this mod you will need to jumper that connection directly at the tx to get the PA to work.

I have run across various 4-line gear with “added coax and RCA connectors” for speech compressors, scopes, phone patches, and on the SPR-4, FS-4 synth connections. If nicely done I’ll leave them in but too often they are “not pretty” and they are removed.

Paul -

When all else fails..... :-)

Tuning for max output is fine, and quicker than the 'tune and load' sequence. AS LONG AS the
LAST thing you do is DIP THE PLATE!!!

Neutralization is to counteract capacitive 'feedback' through the elements of the PA tubes. It
affects ALL bands, but has the most effect on the highest band. So if you neutralize on the highest band, (where the adjustment is most critical,) the other bands will also be neutralized.

You can neutralize first on 15 or even 20M, which is a broader null and easier to find, and then
'refine' that null on 10M.

Your output on 15 and 10 will improve with neutralization, but you may have damaged the PA tubes
by running off resonance. With good PA tubes in a _neutralized_ PA, you should see 100-110 W.

> OK, I THINK part of my problem is in NEUTRALIZATION and another part is ERROR in how to tune this T4XC up!!
>
> I thought that BASICALLY my dip in plate current went well with the increase in output. But I did not realize that close is not close enough!! For example, when I tune for a complete plate DIP at 0.27 amps this does NOT correspond to maximum output power; max power comes a TAD different on the PLATE dial, but at max OUTPUT the plate current reads 0.42 amps!!! I have been using my WATT meter to tune for maximum output.
>
> For example, on 15 CW in TUNE if I SIMPLY go for maximum OUTPUT I get 130 watts out with 0.46 A (on my T4XC meter), or 42% efficiency. But if I instead tune for the DIP in plate current at max output I get 110 watts out at 0.34A, or 50% efficiency. Minimum plate current is clearly the way to go, but since I am not neutralized I am sending my current HIGHER than it has to be, I am off resonance and screwing everything up.
>
> Also, I was tuning back and forth and back and for the MAX output. If I simply follow the

directions n TUNE:

When you hear hoofbeats, think horses, not zebras!!

Have you confirmed the cable from the wattmeter to the dummy load??? Check at the wattmeter end of that cable to see if you measure 50 ohms. This sure sounds like no antenna past the wattmeter..... You could also connect the cable from the amp to the wattmeter directly to
the dummy load.

I've never seen this happen, so not sure how it would present, but it sure appears that C43 or
C44 has opened. The doorknob caps are chosen for their ability to handle the very high RF currents at this point as much as their high voltage capabilities. I would remove those caps
and check them for capacitance.

Scott -

The correct installation for the FS-4 is to connect the HOT lead to the 'common' wire that runs
to ALL the crystal sockets, and the shield connected to a ground lug nearby. See the manual,
Section 3.2.

Some have mistakenly connected it to a crystal plug and just plugged it in to any socket. This
will 'sorta' work, but the levels are reduced and spurious outputs can appear.

Sherwood used to make a relay box to disconnect the FS-4 when it was turned off, but it's no
longer available.

Damien -

Welcome. Don't worry, most folks on here are NOT experts, but that does NOT mean that they

can't contribute! Contributions take many forms, sometimes only loosely related to Drake radio

gear!! :-) I believe the only qualifying requirement is that you enjoy using Drake gear. It

doesn't hurt if you believe it is the BEST radio equipment, but is not a requirement.

Welcome 'back' to ham radio and the enjoyment of Drake!!

Tossing my 2 cents worth in here...Our group is the only ham group I can

honestly say, I have never seen any attacks on...No egos here.....just

knowledgeable and helpful participants....A breath of fresh air, in a jungle

of ham groups that the testosterone levels push the competition on who can

discredit who's knowledge.

No question ever asked here, is considered too small to start a session, and

multiple views/ideas on solving an issue, are welcomed, rather than scorned.

Welcome aboard!

Joe Wolfe - W7RKN

20566. tr7 questions

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-04-30 15:50:34 UTC
From: geoffrey mendelson
Topic: 20566 Message: 20566

Thanks to everyone for all the help with my previous questions.
Here's the situation as far as I can tell at this time:

1. The tuning gears are jammed. I can move the brass ring around the main knob and it changes frequency, so I am hoping the PTO is ok, and it's just someone forcing the knob too far to the low end and jamming it or the oil on the nylon gear problem similar to the SPR-4 I repaired.

2. AM and LSB seem to put something out. I can't tell as with the jammed VFO, I can't find a frequency I can receive to check it out. I have another way around it, but have not done so yet.

3. USB puts out 100 watts with no input. If I yell into the microphone the power out changes slightly. There was some sort of RTTY mod done to it, does this sound familar? I have not opened the bottom extension to see if anything is there.

4. The meter bulb was replaced with a soldered in smaller bulb stuck in the socket. I may remove it and go back to the original if I can.

Any advice?

Anyone know of someone who works on Drake rigs in Israel?

TIA,

Geoff.

20567. Re: T4XC plate current too high?

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-04-30 16:08:58 UTC
From: <rochep@...>
Topic: 20484 Message: 20567

I think I got it. So if I tune for maximum output in a NON-NEUTRALIZED transmitter I will indeed have lots of power out, but the current flowing through the PA tubes is much higher than it should be because it is not resonant (i.e. the plate is not "dipped"). But if I tune for maximum output in this same NON-NEUTRALIZED transmitter and at the END of my "tune-up" I dip the plate I will find my plate current is dipped to a "reasonable" level, my power output might be a bit lower, but my efficiency is better (closer to 50%) and the tubes are happier?

I was just tuning for max output and CONTINUOUSLY increasing gain/altering PLATE for max smoke/increasing LOAD till not more output, etc...

Thanks for clearing it up!!!

The simplest thing to do is neutralize the finals, and then the dip and
max power out will coincide at the same place.

Garey-

Since there are two doorknob caps in parallel, I pulled one out at a time leaving the other one in place to check for any change ... the result: No change. I wouldn't think both would fail at the same time.

It seems like I'm missing something obvious.

I use the cantenna, connecting cables and an external watt meter frequently with various amplifiers, don't suspect anything there.
Thank you for your ideas.

I'll keep plugging away.

The PTO is fairly simple. The 'silver' shaft turns the lead screw in the gearbox, directly. There is a threaded follower on the lead screw that moves back and forth as the lead screw is
rotated. The follower is the piece with the spring from its top to the shield can. If the shaft is turned too far, the follower can be jammed against the front or back wall of the gearbox. If it's jammed against the back wall, turn the silver shaft ccw to release it. If it's to the front, it can actually get off the threaded area and wedge against the front wall of
the gearbox.

The 'extra' power is often spurious output generated by the PA oscillating on its own, and almost certainly NOT on the frequency you think it is!!

The most important thing is that the PLATE is DIPPED, as this indicates resonance, meaning that
the power is being transferred from the PA tube plates to the load. ANY increase in power 'away' from the dip is suspect and NOT good for PA tubes.

Thanks, I appreciate it.

Do you happen to remember if it has been turned all the way to the low
end, which direction it is jammed?

TIA,

Geoff.

20573. RV-75 Cable Question

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-04-30 17:37:18 UTC
From: Wayne Bethoney
Topic: 20573 Message: 20573

I have a RV-75 question: The two coax cables inside my RV-75 are reversed from the digital board to the analog board. That is on the analog board the center conductor on the coax goes to ground where as on the digital board it does not. The schematic shows it that way. Was wondering why? My VFO drifts. I checked out the digital board via the manual alignment and it is fine. Any help is appreciated.

Thanks Wayne/WC1C

Michael -

OK. It sure acts like there is no load past the wattmeter, except for the minimal reflected power.

I agree that it's unlikely that both caps would fail, and a single cap would work fine on the
higher bands, especially.

Does it change on different bands??

Garey -

Wanted to let you know that the 400 Watts the L4B amplifier puts out warms up the oil in the Heath Kit Cantenna.

I get the same results on all bands unless the results are so subtle that I have not noticed them.

1. I get a nice, rather sharp dip in the plate current.

2. Load capacitor all the way counter cockwise for maximum RF output.

3. Just 300 - 400 watts.

Damien, this is the best group I've ever been in, bar none. Learning goes two-way here and all are good guys. Welcome to the group.

Oh, and don't be intimidated by the expertise generally shown. I've asked many a beginner's question and never been embarrassed by the responses to me. All helpful, all courteous.

Damien -

Welcome. Don't worry, most folks on here are NOT experts, but that does NOT mean that they

can't contribute! Contributions take many forms, sometimes only loosely related to Drake radio

gear!! :-) I believe the only qualifying requirement is that you enjoy using Drake gear. It

doesn't hurt if you believe it is the BEST radio equipment, but is not a requirement.

Welcome 'back' to ham radio and the enjoyment of Drake!!

>

> Got my licence in 1967 and operated SSB on the HF bands until 1975. Used an early commercial SSB transmitter, the British made KW Viceroy, which had an excellent reputation at the time and with which I was very happy. (I wonder if any are still in use?) For receiving I had an immaculate AR88D initially, absolutely marvellous but not designed for SSB of course, followed by an Eddystone 840C which was not designed for SSB either and then a mediocre Star receiver.

>

> G3PTN, designer of the Zygi beam, suggested I find a good Drake R4A. This I did and could not have been more delighted with that receiver which was light years ahead of anything I had used before. So a lifelong Drake fan was born.

>

> In late 1975 I had to move city for job reasons, then I had to move again and yet again. Marriage and bringing up a family occupied time of course and I also started a small business which never really prospered but gave me a good living as long as I worked 60 hours a week and travelled a lot internationally. Ham radio was reduced to scanning Radcom (RSGB monthly mag') when I had time. Suddenly, now retired, I realise 38 years have gone and I do not know where! No idea!

>

> So I am now putting together a station and the main thing missing at the moment is an antenna! So the most important thing comes last? Blame the winter for that. So far I have a very clean TR4, AC4R, RV4C, MS4, MN2700 and even a Drake 7075 Mic'.

>

> Finally I should mention that I have been fortunate enough to make a few contacts recently when on holiday in the Bahamas with the reciprocal call of C6AXE. This confirmed my interest in the World's best hobby, not that I really ever had any doubts. I am rag-chewer rather than a DX man and hope to meet some of you on air.

All the way to the low end of the band puts the follower up against the front of the gearbox.

You can get it 'back on the rails' by holding it at the end of the threaded portion of the lead
screw to get it started.

The DR-7 board is going to have to be removed to do much of anything with the PTO. It comes out
fairly easily by disconnecting all the connectors (photos and/or drawings first as the connector
are not keyed or marked) and lifting straight up. There is a row of pins down to the parent board along the left-rear edge, another at right angles to the left edge about halfway to the
front, and three more over near the middle. The radio will NOT work with the DR-7 out unless you
have the jumper board (a part of the board extender kit). You have to be careful replacing the
DR-7 to ensure that the pins all line up with the sockets as they are not easily visible. Verify that they are straight, and check for cracked solder where they solder to the DR-7 once
you have it back in. There is much information in the list archives regarding this. The Search box at the top of the main list page searches 'conversations' (messages) very quickly.

Really strange behavior... Sounds exactly like what happens if the LOAD control is fully CCW,
and reducing the LOAD capacitance should cause the PLATE current to increase. Just what I would
expect if the LOAD variable was NOT turning.

I'm assuming the PLATE current you are seeing is consistent with the amount of output power you
are seeing.?? About 400 mA in CW??

Yes, except the grid current is way too high for such a low output.

230 ma grid current.
250 ma plate current
2500 plate voltage
625 watt input
About 350 watts output
56% efficiency

The answer must be resting somewhere within the excessive grid current reading.

Are you sure someone didn't attempt to modify that amp for class B or C? If successful one would expect more power out, but this might explain the low drive required (20w you said?) to obtain the specified grid current.

Just a thought

Chris

Mike

One suggestion would be to check the setting of R16, the grid current meter calibration pot. If this pot or adjacent circuit has a fault, the extrapolated grid current reading will be in error and could possibly read higher than actual. It appears from the schematic that the L4B determines grid current indirectly.

The L4B manual has a section (section 5) that describes how to check the calibration of the grid and plate meters and setting of R16.

Subject: Re: [DrakeRadio] L4B - low output with new tubes.

Yes, except the grid current is way too high for such a low output.

230 ma grid current.

250 ma plate current

2500 plate voltage

625 watt input

About 350 watts output

56% efficiency

The answer must be resting somewhere within the excessive grid current

reading.

I've been following this thread for a couple of days.
Personally, I'd be really suspicious of those "new" tubes.
Where did you get them? Have you tested them on a
good mutual conductance tester? Do you have a decent
pair of "old" tubes to compare just to see if you get a
sharp dip? Also. Are the "new" tubes NOS US made
or are they foreign??
Just a thought.

Chris -

Thank you for your input Chris.
The only modifications this amplifier has is the surge protector and soft key mods from Harbach electronics. Removing the surge protector produced no change in performance.
I don't have a schematic in front of me so I'm going from memory at this point:

When the amplifier is keyed, the cathodes become common to the grounded grids through the T/R relay and a 1 ohm 10 watt resistor, and the grids are allowed to conduct with adequate drive. When not keyed the cathodes receive +120 volts from the T/R relay and power supply effectively cutting off all plate and grid current .

The excessive Grid current is a result of power not being coupled out of the amp. High Grid current is also a direct symptom of a LOAD capacitor at full capacitance. The Drive power is
just going through the Cathode to the Grid to ground instead of going through to the output.

I would certainly stay on CW rather than SSB to minimize stress on the entire amp/power supply
system. No reason for 2500 V!

Thank you Joe, yes, before I put those tubes in they were functioning at
1500 watts no problem in a Henry 3K-A amplifier

Point well taken Garey.

The L4B appears to be acting as an amplifier that doesn't have high anode voltage. But it does have high voltage. Without high voltage there's no Amplification Factor and the grid current can go excessive even with small amounts of drive... The electron cloud is simply circulating around the grid/cathode input circuitry. (the input SWR is flat as read on a Yaesu FT1000D)

The higher the anode voltage the Less the grid current reading.

I really don't have any reason to suspect that the amplifiers high voltage meter reading is wrong, but I'm thinking of purchasing a high-voltage probe for my volt meter to be sure. No, wait a minute, the dummy load is warm... there is high voltage!

I'm starting to think there may be something wrong with the loading capacitor. How in the heck does that go bad?!

From: Garey Barrell
Topic: 20499 Message: 20588

Just reduce the drive. I seriously doubt that the HV is far enough off to matter. The SSB just
further stresses 'everything' in the amp and PS and serves no purpose at this point.

Take a look at the RF chokes on the Grids. They should have three distinct winding sections.
If it's all one winding they may have 'collapsed' and are no longer chokes. We're grasping at
straws!! :-)

73, Garey - K4OAH
Glen Allen, VA

20589. Re: [DrakeRadio] L4B - low output with new tubes.

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-04-30 20:31:57 UTC
From: Michael Engstrom
Topic: 20499 Message: 20589

I checked each RF Choke early on and reported that they looked good... no hot or burn spots. They looked fresh. I will check them again Garey with the new information you provided. Thank you for your input!

There is no way this amplifier is not going to get repaired!!! That's a double negative... it will be repaired!

The answer remains hidden in the excessive grid current. The plate portion of the tank circuit resonates and the plate current dipps sharply as expected. Is it the loading section of the pi-net that is failing to deliver the circulating RF currents to the load. Like it ain't loading up man!

Do you happen to remember if it has been turned all the way to the low
end, which direction it is jammed? Geoff.
Geoff, As I look at one it would have been turned all the way to the
right. Garey already said the DR7 board has to come off....you can see what
happened at that point. Carl wd8nhk

I believe "cathodes" in this instance means filament. The 3-500 series is not indirectly heated and thus has no cathode per se.

Chris -

Thank you for your input Chris.
The only modifications this amplifier has is the surge protector and soft key mods from Harbach electronics. Removing the surge protector produced no change in performance.
I don't have a schematic in front of me so I'm going from memory at this point:

When the amplifier is keyed, the cathodes become common to the grounded grids through the T/R relay and a 1 ohm 10 watt resistor, and the grids are allowed to conduct with adequate drive. When not keyed the cathodes receive +120 volts from the T/R relay and power supply effectively cutting off all plate and grid current .

Copy that. Yes filaments.

Thank you for your thoughts.

20594. TR-4CW CALIBRATOR ON 40M

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-04-30 23:22:55 UTC
From: David Nichols
Topic: 20594 Message: 20594

I believe I have it figured out now. The calibrator is working fine on the other bands. The band switch is clean and looking like its working as it should. The calibrator wire is in the proper location and not touching anything.

Then I found the calibrator signal on 40 meters coming in very well. The problem is, I was looking for it at 7.300 and found it at 7.335. I thought about this for a minute and then I plugged it into the service monitor. I hadnt checked it out for frequency settings yet. Well, 40 meters appears to be off by .165 kc's. Not because of where I hear the calibrator signal but because of the signal on the scope. The spectrum analyzer put it out in right field!

I set the analyzer to 7.200 and when I get the signal lined up at 7.2 my dial scale is sitting on 7.035 and I do receive a good strong calibrator signal there. I dont know of any way to adjust the frequency so Im guessing I need a new 40 meter crystal. I just dont want to do the math when Im working 40 meters.. hi hi. I found 20 meters off a few kc's too but just a couple. The 40 meter crystal is on a walk about. hi hi

Sounds like a bad crystal to me.

Had a TR-3 that had one that was off by about 20 kc. It happens.

The easiest way to both pull the DR-7 and work on the PTO is to pull the bandswitch shaft back and hinge the front panel assembly down as described in the service manual. You don't need to pull the shaft all the way out, just far enough to clear the hole in the front panel.

Michael -

Something was pointed out to me that I had forgotten. The BAND switch is of course the input
wafers and the output wafers. They are 'ganged' by the bead chain. They can get out of sync if
the chain has been broken and repaired incorrectly, or in some cases just slipped.. Have you
verified that the input and output wafers are on the same band???

A question then:-

At what point do we declare a crystal as being too far off frequency and requiring replacement? Which I guess is the same as asking "What is the typical dial error seen between bands"? And is/was there a factory specification or tolerance value for this when new?

On my TR-4C I have the following (using 3.5 as the reference):-

3.5 }
7.0 } All within 1KHz
14.0 }

21.0 ~= 8KHz out
28.0 ~= 15KHz out
28.5 ~= 15KHz out
29.0 ~= 17.5 KHz out

A crystal is 'too far off frequency' when you get tired of slipping the dial skirt every time
you go to that band.! This assumes that the crystal is oscillating 'cleanly' at the 'off' frequency. These are mostly 3rd overtone crystals, so can get 'squirrelly'.

The original specification was +/- 0.003% or +/- 210 Hz at 7 MHz. Crystals from International
Crystal Manufacturing will easily meet this specification.

As for your numbers, NO BAND crystal is involved with 80 and 20M, so I would surmise that your
40M crystal is the outlier.

I thought maybe it might just have a bad connection in the socket on the 40 meter xtal. But apparently not. I dipped all of the crystals in deox and worked them back into the sockets a few times. This didnt seem to fix the problem with 40 meters so Ill have to order a new one tomorrow.
Maybe Ill see if I can get the old one apart so I can take a look at it. I dont believe Ill be able to repair it but I like to see how things are made.. hi hi
When I got this TR-4CW I wasnt thinking I would get this much fun out of it..

I'll second that. I've come across many Twins using "funny" crystal frequencies that were obviously made for other applications, but will cover band segments on the Twins. It all depends on what your tolerance is to having the dial read "off" or how far you want to keep cranking the PTO knob to get it "in".

I took one apart recently. The construction is interesting - it looks almost like a piece of plastic with very fine wire going to a couple of spring contacts that connect to the pins.

It makes you appreciate how good the science is that can cut one of these for a precise frequency like they do.

Another mod for bouncy meters.

Yes, the cap across it is a good idea. Even Hewlett-Packard used that trick in their gear. And yes, keep its voltage rating as low as possible. I've seen caps in such service that became unformed due to lack of voltage and time of voltage application. (I don't offhand know if bipolar and nonpolarized electrolytics would suffer less from this.)

Curing bouncing can also be done with a series and a parallel resistor.

To wit, I once had a MIL surplus meter, scale marked 0-50 uA. I opened it up (of course!) and found a parallel-connected resistor inside. (I don't recall the value of it, too long ago.)

When removed, the meter FS'd at 20 uA! Astonishing! Most sensitive D'Arsonval (moving coil type) movement I'd ever seen.

Except...it bounced like crazy. So I had to return some parallel resistance to it.

I could achieve under-damped, over-damped,and critically-damped action of the meter by varying the parallel resistor value.

(This is an exact analog to mechanical systems consisting of spring, mass, and viscous damper. We are equivalently changing the damping. Overdamped means that the meter pointer takes a long time to reach its reading; underdamped means meter moves too fast, over-shoots its reading and bounces; critically damped means the point gets to it reading as fast as possible with no overshoot.

As putting higher/lower parallel resistance on the meter will result in higher/lower readings, if you can manage it, circuit-wise, you can add or change a series resistor to get readings back to accurate again, and can have the meter action you want, slow to fast and all in between.

The Drake meters use the cheaper moving iron vane type movements. More rugged but liable to have poor damping characteristics. However in this non-critical app, it's just fine.

P.S. I ALWAYS check metering series and shunt resistors first thing when a piece of older gear comes into the shack. Some are off the mark, sometimes in the undesirable direction.

Hello David,

I was going to suggest you look further away for the cal signal as I had an R4b with bad band crystals. Some were more than 30kc off and was very confusing to find the correct cal signal on the dial skirt. I ordered 3 crystals from ICM and now all are in line. This is more difficult when the cal signal is at 25kc and you don't know which is the correct one for the freq you are looking for. That is why I set my calibrator to 50kc.

Ski-WB8YXI

I think the OP reported that the calibrator could be heard if the bandswitch was not quite at the detent. That sounds more like the switch rotors are not quite aligned with the stators. I think the TR-4 switch has a right angle drive and it would be worth looking at that. Also, check the long bolts that hole the switch together, they may be loose allowing one or more of the stators to move around a little. The fact that cleaning the switch helped suggests there is still a problem with it. I found the bandswitch in my TR-4 was very fussy and needed repeated cleanings and some tightening to work reliably.

What a great observation Garey!
I did a cursory ohmmeter check at one point, but it is worth really focusing on.
That could account for the symptoms - if the output tank is out of sync with the input selection. I'll put a meter on it and confirm...

but I do get a dip at the appropriate point on the plate tune control on the front panel. For example, if I've selected the 40 meter band, there is a plate current dip right at the 40 meter red pointer area on the front panel. If I select the 80 meter band, there is a plate current dip at the 80 meter band position on the front panel. Since the plate tuning and loading are on the same switch section, and cannot get out of sync with each other, my hopes are low.

Again, what a great observation Garey. I really want the input and output to be out of sync! I will investigate and report back.

Damien -

Welcome. Don't worry, most folks on here are NOT experts, but that does NOT mean that they

can't contribute! Contributions take many forms, sometimes only loosely related to Drake radio

gear!! :-) I believe the only qualifying requirement is that you enjoy using Drake gear. It

doesn't hurt if you believe it is the BEST radio equipment, but is not a requirement.

Welcome 'back' to ham radio and the enjoyment of Drake!!

20609. bandswitch re: L4B - low output with new tubes.

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-01 12:53:00 UTC
From: Evan Rolek
Topic: 20499 Message: 20609

Michael,

The output bandswitch section basically "can't get out of sync with itself". Why? There is a flat on the shaft so that the bandswitch pointer knob has to be in the right position with respect to the contact configuration for the output pi-network. Hence, the pi-network will function properly. However, if the cogged belt connecting that switch to the input wafer is "misaligned", then the input wafer could conceivably be on the wrong band position. This would result in the wrong input coil being selected for the respective bands with one band having no input coil. This would result in reduced drive to the amp and who knows what other problems, although it might still function depending on the harmonic relationship between the input coil and the output pi-network.

Too, checking the calibration of the grid current metering circuit should be a basic check.

73,

Evan, K9SQG

20610. Re: T4XC plate current too high?

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-01 13:06:04 UTC
From: <rochep@...>
Topic: 20484 Message: 20610

I have a question about how to really tune up a Drake TX. The procedures outlined in the T4XB manual and T4XC manual are different.

The T4XC manual says:
Peak RF TUNE and then dip the plate with MINIMAL GAIN
Set GAIN to the 12:00 position, re-dip plate and increase LOAD till no more output.
Re-check RF TUNE

The T4XB manual says:
Peak RF TUNE and then dip the plate with MINIMAL GAIN
Increase GAIN until plate current no longer increases
Adjust LOAD and PLATE for maximum RF out (this will be at plate dip), re-dip plate

It is step 2, the GAIN control setting is the main difference. Is one way better than the other, and does it matter which system I use for either transmitter? When switching to CW I simply increase the GAIN until I have either 100 watts out or 0.34A of plate current and then re-dip plate.

Also, is poor EFFICIENCY an indicator of bad finals? Tuned into a dummy load on 40 meters with my T4XB the efficiency with 80 watts output is 55% (0.22A), but on my T4XC the efficiency with 80 watts output is 35% (0.35A). The neutralization on each seems to be about right on.

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-01 14:34:21 UTC
From: Garey Barrell
Topic: 20484 Message: 20611

Paul -

I don't think it's very important either way..... I understand the reasoning for both procedures. The PRIMARY goal in tuning up is to keep the PLATE current dipped, minimizing 'out
of resonance' (undipped) time to the least possible.

1. The C method is get a little plate current by increasing the GAIN and dip the plate. Peak
the RF TUNE. Then set GAIN to 12:00 position (which is past the point where the ALC kicks in
and limits the output) and alternately adjust PLATE and LOAD until max output is reached.

2. The B method is a little more 'old school'. Start out by increasing the GAIN for a 'little'
power and dip the plate. Peak the RF TUNE. Then increase the GAIN (used to be 'increase the drive') to maximum output. Adjust PLATE and LOAD controls for maximum output, finishing by DIPPING THE PLATE!

So essentially the procedure is the same. The C method sets the GAIN past the known point of
ALC action, while the B method sets the GAIN just 'to' the ALC point. Again, the only thing that really matters is that the plate is DIPPED.

Yes, efficiency drops off as the tubes age. It's first apparent on 10M and proceeds to the lower bands over time. The transmitters are functionally identical.

Damien,

Welcome back to ham radio and Drakes. As others have already said, you

will find this a welcoming group, and even dumb as I am, they let me

contribute once in a while to things. I too am a consumate rag chewer

and hope to work you one day on the air. I have a room FULL of gear,

and growing daily literally, so we should have NO trouble, HI.

Again, welcome to the group, and enjoy those Drakes. You have a fine

start again. Antenna is next, but don't wait too long on the warm

weather or it won't work properly. I put up my beam this winter between

storms quite literally but it did warm some!!!!!!!

Dan, thank you for your welcome and for taking so much trouble in explaining about your successful servicing of Drake equipment. I am red/green blind myself, as lots of males are for some reason, so can understand your frustration with resistor colour codes. Strangely I managed to pass a lantern test many years ago but I cannot make head nor tale of those weird colour test pages! Isshara or something I think they are called.

Your comments on Drake & Collins receivers versus modern Japanese transceivers are most interesting. I wonder how well the TR4 line receivers compare with the R4 receivers. It is a lifetime ago but I seem to remember my R4A had some notch or passband shifting facility which was most useful but the TR4 does not have this.

Sorry to hear you are disposing of so much of your lovely vintage gear but I am sure you have your reasons.

Thanks again for all your information.

Subject: Re: [DrakeRadio] Damien G3XER delighted to join the group

Damien

I might add, that I am likely one of the least experienced, at repair work, here on the list. A couple of years back, I ran into a unique situation, where I did something stupid, and burned up a friend's R4C, which he was wanting to sell. I wound up paying full price, for the radio I had broken. Since my repair knowledge was very limited, and certainly I was more familiar, and comfortable, working in a transmitter, than a receiver, I suggested that since it was otherwise a seemingly good radio, that maybe I ought to part it out, in attempt to get as much of my cost, back out of it, as I could. I am color blind, and wire color codes, always frightened the heck out of me. It's not that I wanted to part it out, but my wallet was overtaking my thought process, at that point.

After a proper chastising, from a few of the good members here, and encouragement from others, who were convinced that they could help guide me through it, I tackled the issue. It turned out to need a transformer, and some diodes in the PS. AND, gave me enough confidence, that I tackled two other receivers, shortly after that.

Now, I sold the receiver, for about what I paid for it (I think I sold it for $10 less than I paid), and really only lost the cost of the parts that I broke. A pretty decent deal, since it kept a very nice R4C in use. But, the best part, was when the fellow who purchased it, called back, and said that he was using it, and liked the receive so much, that he decided to try comparing it, with his Kenwood TS-950SDX. When he did so, he found the R4C, to be a superior receiver to both it, and an Icom IC-756ProIII.

One of the other receivers that I tackled, because of the wonderful guidance I received here, was a Collins 75A-4. When I sold it, the purchaser, a Collins Collector, said it was the best receiver in his shack, at the time. The third, is the Hammarlund HQ-150, that currently graces my shack, as my only remaining tube type receiver, in everyday use.

I have THIS GROUP, to thank, for the help and encouragement. My best advice is this. If/when you do any work, on your Drakes, please, take AMPLE NUMBERS of good resolution photos, and post descriptions of your problems, solutions, and results here. You will have access to an invaluable resource, in this group.

Even though I have recently sold most all of my Drake equipment, with the rest soon to follow, as well as most of my Collins gear, I will remain a member here, as this is, as mentioned, the finest group, of it's type, available, anywhere.

73,

Dan

John Sehring wrote:

>> Yes, the cap across it is a good idea. Even Hewlett-Packard used that trick in their gear. And yes, keep its voltage rating as low as possible. I've seen caps in such service that became unformed due to lack of voltage and time of voltage application. (I don't offhand know if bipolar and nonpolarized electrolytics would suffer less from this.)

Drake used this technique on the 2-NT transmitter.

>> The Drake meters use the cheaper moving iron vane type movements. More rugged but liable to
have poor damping characteristics. However in this non-critical app, it's just fine.

You haven't seen a 'bouncy' meter until you try to tune up a transmitter using one of the old
Shurite meters like those used on the Heath AT-1, DX-35 or the WRL Globe Chief, etc. Almost all
of the Drake meters exhibit a nice, smooth response similar to a moving coil movement. However,
'some' go crazy and emulate the old Shurite meters!! I don't know, but I suspect that the Drake
meters had some sort of grease or heavy oil on the pivots to damp them. The TR series meters
seem to be more prone to this, possibly because of the considerably higher heat relative to the
twins. There are very heavy Silicone oils with 'weights' in the hundreds or even thousands that
were used in the era for damping tone arm suspensions (yeah, I know, "what's a 'tone arm'"...
part of a 'record player' ... never mind).

>> P.S. I ALWAYS check metering series and shunt resistors first thing when a piece of older
gear comes into the shack. Some are off the mark, sometimes in the undesirable direction.

Absolutely! ALWAYS do this, right after you check to insure that the 'correct' fuse is in the
fuse holder!! :-)

Topic: 20505 Message: 20618

Ok, I did it…
I replaced the 2nd IF board ver.1 of my TR-7 with a newer board ver.2 (that I got from a second TR7 that I bought - for parts - at a very low price). First, I replaced the 8 electrolytic capacitors with fresh ones, then I modified the PBT board by replacing/removing the two resistors to adapt the BFO level (thanks everybody for the hint). I finished the work aligning the IFs and the AGC / S-meter circuit. The board worked immediately, and my impression is that the audio quality is better (ok, it maybe a placebo effect :-))… also the action of the AGC seems to be smoother.

One thing that can be of general interest is that on BOTH boards (i.e. the old ver. 1 and the new ver. 2) I had to replace the same defective (noisy) transistor Q1113 (2N3904), the preamplifier in the audio stage. It causes a continuous low-frequency rumble/crackling, that is most audible when the RF gain is set at minimum (i.e. completely CCW). The rumble level was independent on the volume setting, indicating that the problem was beyond the volume pot. If you are experiencing something like that on your TR7, you know who the culprit is… I wonder if this is something related only to the AF stage, or it is a common problem with aging 2N3904s…. this would be a nightmare, since Drake used A LOT of those transistors in the TR7…

Again, thanks everybody for the hints and suggestions !

73,
Michele

Hi Keith,

Nice to hear that there are a few U.K. Drake fanatics. Thanks for letting me know and for your kind welcome.

Maybe there is a case for an informal Drake get together at Newark in September!

Hello Damien,

You will find there are quite a few UK Drake fanatics on this list, they may well not be often seen,

But they read the ?posts?

Welcome to a very nice facility run by Gary, a lot of very useful info appears.

Subject: [DrakeRadio] Damien G3XER delighted to join the group

Hi all,

Garey kindly invited me to join and I am very pleased to do so though a little concerned that I have far too little knowledge to contribute much! The welcome email suggests I introduce myself so here goes.

Got my licence in 1967 and operated SSB on the HF bands until 1975. Used an early commercial SSB transmitter, the British made KW Viceroy, which had an excellent reputation at the time and with which I was very happy. (I wonder if any are still in use?) For receiving I had an immaculate AR88D initially, absolutely marvellous but not designed for SSB of course, followed by an Eddystone 840C which was not designed for SSB either and then a mediocre Star receiver.

G3PTN, designer of the Zygi beam, suggested I find a good Drake R4A. This I did and could not have been more delighted with that receiver which was light years ahead of anything I had used before. So a lifelong Drake fan was born.

In late 1975 I had to move city for job reasons, then I had to move again and yet again. Marriage and bringing up a family occupied time of course and I also started a small business which never really prospered but gave me a good living as long as I worked 60 hours a week and travelled a lot internationally. Ham radio was reduced to scanning Radcom (RSGB monthly mag') when I had time. Suddenly, now retired, I realise 38 years have gone and I do not know where! No idea!

So I am now putting together a station and the main thing missing at the moment is an antenna! So the most important thing comes last? Blame the winter for that. So far I have a very clean TR4, AC4R, RV4C, MS4, MN2700 and even a Drake 7075 Mic'.

Finally I should mention that I have been fortunate enough to make a few contacts recently when on holiday in the Bahamas with the reciprocal call of C6AXE. This confirmed my interest in the World's best hobby, not that I really ever had any doubts. I am rag-chewer rather than a DX man and hope to meet some of you on air.

73 to all,

Damien G3XER

Hey Joe,
I do fully intend to sell this amplifier when I get it working... bought it with the idea that the tubes were bad... but the tubes are good! So there is something else going on.... which at this point seems to be the understatement of the week!

Your voltages look reasonable. Do you have a DMM??

Try measuring the DC voltage across the meter terminals. You should measure 1 VDC or less, with
RF GAIN max CCW you should read 1 volt.??

20626. amp meter swing, TR-4C

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-01 17:39:51 UTC
From: David Nichols
Topic: 20626 Message: 20626

This working for me, its up to you if you want to try it and see if it works for you. My meter was swinging back and forth like it was a pendulum. It took almost forever to come to rest so I could make a meaningful adjustment. I bought a new set of meters and went to work with what I was doing. When I got some time to inspect the pulled meter I opened it up and figured out how it worked. I did not figure out what it should take for full scale reading. I figured it needed fixed when I started so if I couldnt fix it "so what". This aint my first meter, Ive been into a few and can set them up to full scale just fine. In any event, if you open your meter up there are some steps you need to be aware of. First off they have a magnet in them, while in this meter configuration it may not be extremely critical in other meters it is very critical. It only takes one extremely tiny magnetic particle to make a meter movement hangup or stick. You MUST have a clean work area. Cover your bench with fresh paper towels or something that is new. You may think you have a clean work area but you dont if you dont cover it with something new. The new cover must be large enough that magnet doesnt reach out and suck some microscopic sliver into the case. No, its not a super magnet but you cant see those little things without a good eye and a magnifier lens. Dont create a problem you dont already have. I wont attempt to explain how these work and Im sure Ill get my share of detractors with what Im saying. These meters pivot on a shaft with pointed ends. The ends fit into very small divots, if you manage to get one of the ends out of place it must be put back. Oh, did I mention, they are delicate. A heavy hand will ruin your meter in a heartbeat. To give yourself some idea about the meters movement place your digital ohm meter on the terminal screws mine measures about 230 ohms. By the way, so does the S meter. If you put the leads on backwards the meter will go backwards so turn the test leads around. Make note the reading you got on the amp meter. You want it to be the same after your done playing with it. Unless you know what the full scale setup is of course. Any way, as I was saying the need swings on pivot points. It is my contention that over time and many heat-up and cool-down sessions the meter frame has expanded and loosened up this pivot point a little. So the trick is to tighten that pivot just a little. If you look into the meter case you will see a brass frame at the back of the needle. It will have a zero adjust slot on it. The zero adjustment has been set in place with some kind of clear coating. It should not move simply by touching it. You need to press down on that little piece of brass just a little bit. A big push will lock up your meter and will require you to work more than you should. Just give it a little nudge like a fly landed on it and see if it made a change. If you get it to tight it wont go to the setting you got with your ohm meter. For the nay sayers, Ive already done this... you cant tell me it cant be done.

Topic: 20499 Message: 20629

OK, how about this?

Step 1: First isolate and check the loading capacitor with a capacitance meter to verify that each section produces the correct capacitance change when rotated. If OK, restore the connections and go to step 2.

Step 2: Lift the connection from the C22-C24 junction to the tube filaments. Connect a piece of RG-8X co-ax through a suitable, known good .01 uF capacitor to that point and put a PL-259 at the other end. Connect it to the exciter and operate the amplifier, thereby either eliminating or exposing the input circuitry as the problem area.

Step 3: Obviously if it works correctly with this setup, the problem will be at least isolated to components in the input or ALC circuitry. OTOH, if it continues to produce similar goofy results, there are at least a lot fewer components to suspect. I'd start with checking capacitance of each of the 200 pf grid bypass capacitors individually, then RFC1, RFC 3, and RFC 5.

Step 4 (grasping at straws): Perhaps there is a possibility of center conductor migration in any co-ax interconnections within the amplifier which are routed around a tight radius (if there are any). While this condition may not produce a short to the shield, the impedance hump at that point might be enough to cause tuning issues.

20630. Re: [DrakeRadio] L4B - low output with new tubes.

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-01 20:37:45 UTC
From: w7fe
Topic: 20499 Message: 20630

P.S to my previous post:

Step 2 may require that you use a matching network/transmatch/"tuner"
between your exciter and the connection point I suggested. The impedance at
that point is likely beyond what your exciter will properly load.

Stu

20631. Re: [DrakeRadio] L4B - low output with new tubes.

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-01 20:50:37 UTC
From: Michael Engstrom
Topic: 20499 Message: 20631

Thank you Stu. A lot of really good ideas to implement. I need to up my troubleshooting equipment with a capacitor tester.

Meantime... I keep thinking:

What would cause those tubes to draw so much grid current with only 5 - 10 watts of drive?

No amplifier I have ever come across would do that unless there was no or low plate voltage. But the arithmetic proves I have plate voltage.

If we could answer this question:

What would cause those tubes to draw so much grid current with only 5 - 10 watts of drive?

the problem may be solved...

The explanation for the Grid current is that power is going into the tubes, but not being coupled out. For an as yet undetermined reason, you have a couple of very large diode rectifiers with an input network that matches them to a 50 ohm input. So the RF is 'detected'
and passed to ground, displayed as Grid current.

This would normally indicate a mismatch on the output network, and as a result not coupling power to the load.

This is normally the result of no Plate voltage, an open DC block/coupling cap between the tube
Plates and the Output matching network.

If you had a return loss bridge, you could connect a 2-2.5k resistor from the DC block cap to
ground, (disconnecting the tube Plate caps or removing the caps,) and then apply RF at 50 ohms
through a return loss bridge to the OUTPUT antenna connector and see if you could adjust the
PLATE and LOAD caps for maximum return loss. If you have a big enough resistor, you could actually drive RF from your transmitter and adjust for minimum reflected power.

I still think we're missing something obvious, but I'm #&^$^% if "I" can see it from here.! :-)

Mike

You seem convinced that the grid current metering circuit is reporting correctly.
Did you already check it calibration ?

Thank you Stu. A lot of really good ideas to implement. I need to up my

troubleshooting equipment with a capacitor tester.

Meantime... I keep thinking:

What would cause those tubes to draw so much grid current with only 5 - 10

watts of drive?

No amplifier I have ever come across would do that unless there was no or

low plate voltage. But the arithmetic proves I have plate voltage.

If we could answer this question:

What would cause those tubes to draw so much grid current with only 5 - 10

watts of drive?

the problem may be solved...

20634. Re: [DrakeRadio] L4B - low output with new tubes.

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-01 21:49:31 UTC
From: Garey Barrell
Topic: 20499 Message: 20634

I sure wish one of the amp experts that hang around here would pipe up!!!

I'll tell you what I would do if it was MY amplifier.

I'd connect a short piece of wire from _all four_ Grid pins to the chassis, and then apply drive. Leave all the other stuff on there.

These tubes are known to develop 'open circuits' inside the tube pins, external to the envelope. IF ONE tube had _ONE_ OPEN Grid Pin, and it just happened to be the one that the RFC
to ground is NOT connected to, then that Grid is floating.

Far fetched?? Perhaps, but it COULD happen. Only ONE pin on ONE tube has to be OPEN.

73, Garey - K4OAH
Glen Allen, VA

Drake 2-B, 2-C/2-NT, 4-A, 4-B, C-Line
and TR-4/C Service Supplement CDs

Thanks Paul, I need to calibrate the grid current meter so I can check it
off for certain.

I did the same, except I used BC549B. IIRC it was spec-ed slightly better than the 549C for noise.

Garey

Wouldn't we see an offset (out of spec value) in the idling current of the amplifier if a grid is floating ?

May be easier to check if we use a DVM to look at voltages on all four pins and see if any are actually above ground with the amp idling, assuming the pin with the choke is open, the opposing pin would have potential to ground.

Paul - WB2NMI

Subject: Re: [DrakeRadio] L4B - low output with new tubes.

I sure wish one of the amp experts that hang around here would pipe up!!!

I'll tell you what I would do if it was MY amplifier.

I'd connect a short piece of wire from _all four_ Grid pins to the chassis, and then apply

drive. Leave all the other stuff on there.

These tubes are known to develop 'open circuits' inside the tube pins, external to the

envelope. IF ONE tube had _ONE_ OPEN Grid Pin, and it just happened to be the one that the RFC

to ground is NOT connected to, then that Grid is floating.

Far fetched?? Perhaps, but it COULD happen. Only ONE pin on ONE tube has to be OPEN.

Topic: 20499 Message: 20638

Yeah, a C meter is very useful. Last month I bought a Chinese DMM which does AC/DC to 1000V/20A, R to 60 Meg, diode and transistor test, C from 40nF to 2000mF, F from 100Hz to 60MHz, and Temp -40 to 1000 deg C. Autoranging. data hold feature, overload protected, large LCD display, auto shutoff. Check eBay for Vichy VC99. *** $35.50 ***, free shipping, stocked in USA. Can't hardly go wrong , and it works FB.

Still cogitating on a logical answer to the high grid current with low drive enigma - so are a bunch of the other group members, I think. Say, I know a guy in San Diego who is an L-4B guru. Tom, W6KAN. You might email him directly at his arrl.net address. I'll try to get him to chime in on the group, too. If you hear from him first, say 'hi' from me.

73 de Stu, W7FE

20639. Re: [DrakeRadio] L4B - low output with new tubes.

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-01 22:13:52 UTC
From: Steve Wedge
Topic: 20499 Message: 20639

He tried two sets of tubes, though...

I'm still in the camp that thinks power is not getting to the output properly.

Steve Wedge, W1ES/4

Time flies like an arrow; fruit flies like a banana.

All my computers have my signature with various pearls of wisdom appended thereto.

Subject: Re: [DrakeRadio] L4B - low output with new tubes.

I sure wish one of the amp experts that hang around here would pipe up!!!

I'll tell you what I would do if it was MY amplifier.

I'd connect a short piece of wire from _all four_ Grid pins to the chassis, and then apply drive. Leave all the other stuff on there.

These tubes are known to develop 'open circuits' inside the tube pins, external to the envelope. IF ONE tube had _ONE_ OPEN Grid Pin, and it just happened to be the one that the RFC
to ground is NOT connected to, then that Grid is floating.

Far fetched?? Perhaps, but it COULD happen. Only ONE pin on ONE tube has to be OPEN.

73, Garey - K4OAH
Glen Allen, VA

Garey -

I liked your thoughts. Under the scenario you just presented, are you suggesting there may be a parasitic oscillation... and subsequent grid currant unrelated to the driver?

Hi Again Mike,

I am now thinking, as one of the earlier Posts said, You have a faulty relay, or wiring issue around there.

Why you can still get 400W beats me, but it would explain the weird behaviour of the Grid Current.

FWIW

Thanks Paul, I need to calibrate the grid current meter so I can check it
off for certain.

> covers the entire length from the switch. I can get a screwdriver in
> there to pry between the switch and the tubing, though -- there's even
> a break in some sort of collar on the shaft underneath where I can
> slip the blade in, I think.

Just to bring this full circle ... I was able to pry the brass coupler forward about 3/16" or so, at which point it bumped against the hole through the front of the chassis. (It doesn't fit through.) I didn't have a lot of luck prying it backward without bringing the switch lever with it. I ultimately decided that I was far more likely to either break something or damage the face of the radio than I was really comfortable with.

So, I carefully worked everything back into place, and moved on to plan B. The whole reason I wanted to get the face plate off was to clean the BFO switch, so since I couldn't get the face off I disassembled the switch carefully from behind using a pair of bent needle nose pliers to open the tabs, then cleaned and reassembled it. The BFO now switches off cleanly -- previously it would stick on, and it required a thorough working of the switch to get it off, which it would only achieve at the very limit of downward travel.

Until I have a more pressing need to get that face plate off, I guess I'm good to go.

Ethan

20643. Re: [DrakeRadio] FS-4 Question

Yahoo group: DrakeRadio (2014-01 — 2014-05)

From: Whitebear1122
Topic: 206 Message: 20643

Hey Garey, Ohhhh so that's why the FS-4 can still load down the circuit when the aux crystals are not switched in. Thanks for the info! The FS-4 came with a manual but I haven't been able to find it yet as I've had the FS-4 on the shelf for maybe 2 years. Yeah i was initially planning on just using a crystal plug so thanks for heading that problem off at the pass. Listening to 20m SSB with the R-4C as we speak. I've been enjoying using the T-4XC and R-4C on SSB. Haven't gotten her down to cw yet but I will. 73, Scott WA9WFA

From: <rochep@...>
Topic: 20484 Message: 20644

Hmmm, something is up with the finals that came with my T4XC!!!

I put the T4XB finals in my T4XC, everything seemed pretty fine. In TUNE on 80 meters I got 90 watts out with .28A plate current by dipping plate, increasing LOAD till no more output, and then re-dip plate (no extra LOAD adjustment). The LOAD setting was 3 here. 49%, that is fine.

I replaced these finals with my ORIGINAL T4XC (Sylvania) finals. In TUNE on 80 meters with LOAD at ZERO I can dip plate, but then I increase LOAD and plate current and output power go up and up and up until LOAD is at max scale. In fact I have to decrease the GAIN, the plate current is going off scale!!!!

Tubes seem neutralized. Something clearly seems wrong with my ORIGINAL T4XC finals. (When I put them in my T4XB now my T4XB acts crazy and the plate current NEVER stops going up by increasing the LOAD.

So what is going on (besides me ordering a new set of finals?)

paul

Maybe the plate RF choke is open. Just because you have b+ where the meter reads, it doesn't meant it is actually getting to the plates. Unplug the amp, wait at least 5 minutes for capacitors to discharge, disconnect the high voltage cable from the Millen connector on the back of the amp, and measure with an ohmmeter from the center pin of the HV jack to each plate, individually. Should be only a few ohms, might be close to zero ohms. Anything more than a few ohms indicates a problem.

An open plat4e choke would still allow grid current to be drawn when the amp is driven, but no power would be produced. The small amount of power you are seeing might be attributable to feed through power.

Not unlikely for pins on 3-500Z to come soldered from the filament heat either. Just a thought as have seen many!

Scott -

The FS-4 Manual is on the CD. Cleverly hidden in the 'Manuals' sub-directory along with several
others! :-)

Glad you're enjoying it. It IS a nice station....

They're oscillating. Usually a result of improper neutralization, but a bad bypass cap or connection 'can' cause it.

If the other PA tubes work fine in both radios, you have your answer!! :-)

More on my last suggestion: Since you will have the covers off for the plate choke resistance test, be sure to hold down the interlock shorting switch (normally pressed down by the cabinet cover), or else ohmmeter readings could be meaningless. If the interlock is released, it will short the B+ line to ground. The test needs to be made with the interlock depressed (contact points open) .

Forgot to mention that the first time around.

20651. TR-4C RIT Modification

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-02 01:55:50 UTC
From: Steve VK2SJA
Topic: 20594 Message: 20651

Hi All,

Playing around with ideas for adding RIT functionality to my TR-4C.

Any solution is going to need an additional automatic switch that toggles on/off between RX and TX. For the moment I'm thinking small +12vdc relay.

So my question is how to best to go about providing this switching signal/voltage.

I note relay K1 has a switched pair going to pins 5 & 8 of J3. So I could use this. But what functionality/accessory is this used for normally?

I can see that all XMIT K pins are grounded on TX. But I think from memory I measured something like 100+ volts floating on it when in RX. Can you, is it safe to, place a relay coil between +12v and XMIT K with a diode between relay and XMIT K to stop the 100+ volts from energizing the relay in RX? Or is this a dangerous and dumb idea?

A better/best solution would be?

Oh, and before anyone asks. The idea is to replace the non-functional NB On/Off switch with a RIT pot. *WITHOUT* marking or defacing the front panel in any way!! So the control will be labelled incorrectly. Don't care. My radio and I'll know what it does. Most importantly the mod can be reversed back to original at any time.

73, Steve.

One final check -

When the amplifier is "buttoned up", it should draw between 200 and 250 milliamperes PLATE current when turned on and keyed (when the connector marked "vox relay" hot lead is shorted to ground). Make this test with NO RF driving power applied. If it does not do this, there is definitely something amiss in the b+ circuitry

Another thought - it is possible that there is a wire (on the RF choke?) that is partially burned through, making enouigh connection for the b+ meter to read, but failing open when you try to draw some real current.

- Jim, KL7CC

Mike

If the RF plate choke were open, then you would be drawing zero plate current under all conditions. I recall you had plate current so I would anticipate the plate choke has continuity.

This may not be news to some, but another thing I discovered recently is with a properly working board you can adjust the IF Gain pot for exactly S-9 at 50 uV after you have completed the ACG/S-Meter alignments.

Yet another undocumented factory change seems to have been the removal of R1120 (8.2K, next to L1101) to provide a little more IF gain. This may affect the ability to make the above adjustment if R1120 is still in place.

First, I replaced the 8 electrolytic capacitors with fresh ones, then I modified the PBT board by replacing/removing the two resistors to adapt the BFO level (thanks everybody for the hint). I finished the work aligning the IFs and the AGC / S-meter circuit. The board worked immediately, and my impression is that the audio quality is better (ok, it maybe a placebo effect :-))â☐¦ also the action of the AGC seems to be smoother.
>
>
> One thing that can be of general interest is that on BOTH boards (i.e. the old ver. 1 and the new ver. 2) I had to replace the same defective (noisy) transistor Q1113 (2N3904), the preamplifier in the audio stage. It causes a continuous low-frequency rumble/crackling, that is most audible when the RF gain is set at minimum (i.e. completely CCW). The rumble level was independent on the volume setting, indicating that the problem was beyond the volume pot. If you are experiencing something like that on your TR7, you know who the culprit isâ☐¦ I wonder if this is something related only to the AF stage, or it is a common problem with aging 2N3904sâ☐¦. this would be a nightmare, since Drake used A LOT of those transistors in the TR7â☐¦

Lawrence,

I purchased two from Ebay sale number 201082605555. If you google KC9YS, the gentleman that sold these to me on Ebay, has a telephone number and email address linked from WB4HFN's website. These are NOS upgraded knobs and are extremely nice. I have yet to find a new skirt for them though.

73,

Doug - N9XTF

From: <dj_coffman@...>
Topic: 20658 Message: 20658

I have purchased two new B-Line PTO knobs from KC9YS, very nice. Has anyone found any new knob skirts for these units?

If none are made, if there are any nice used ones in the group, I could also use two skirts.

73,

Doug - N9XTF

20659. C4 Console case

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-02 12:25:55 UTC
From: <dj_coffman@...>
Topic: 20659 Message: 20659

I recently received a C4 console that is in rough shape. I would like to replace the case; I have noticed that the MS4 speaker case is close to the same size but obviously none of the holes are there and the speaker case is slotted underneath. One nice feature of the speaker case is that the back upper is rolled to provide support to the metal. The C4 case is very flimsy.

Does anyone have a line on a replacement case or has anyone tried to adapt an MS4 speaker case for this?

73,

Doug - N9XTF

Steve,

If you follow the TR-4C J3 pins 5 & 8 to the AC-3/AC-4 power supply you will see those contacts are connected to the VOX RLY (VOX Relay) two-pin jack used for keying an amplifier. They are isolated contacts so you could use them to key a HB circuit if you are not using an amp.

I don't know how you plan to implement the up/down frequency offset but as Garey Barrell, K4OAH, has advised in the past, the TR-4C PTOs FSK terminal provides for a 170 Hz or 850 Hz shift but only shifts the frequency UP. It is unlikely you could get much more than 1 kHz deviation so this would not be of much use for RIT. Even if you devised a circuit to bias the offset to set the center as "zero" you wouldn't get much more than 500Hz deviation either side of the received frequency.

I applaud your plan to use the NB switch hole without making any marks or drilling the panel to install a control..

Good luck with the project and keep the list posted.

Carl,

The case measurements are hard to get exact as there is some deformation.

W = 10 ¾ inside measurement

H = 5 ¼ inside measurement

Depth = 11 1/8☐ outside and has a ½☐ inset so the face is set in as with the other Drake gear.

Do you have aftermarket boxes or what are you looking at?

Thanks,

Doug ☐ N9XTF

Hi All,

Looking through my Drake stuff boxes. While looking for pieces for a fellow listee.

4 line parts, its a bunch of little miscellaneous stuff, actually most came from when Donnie Garrett was supplying, but now are shown on _www.2bradioparts.com_ (http://www.2bradioparts.com) .

3- # 755 bulbs
1- # 12 bulb
1- Set of shaft couplers with allen screws & wrench
1 -R4A recap kit (13 tube)
1- PTO rubber sleeve
1- ....piece. (not set).. blue difuser for the dial
3- bags worth (total 36) 6-32 black phillips cabinet screws

The above are all new.

Also have a (new to me) set of 3 6GJ5's, GE's (in RCA boxes) that were the back up for the ones I ran in a TR4.

I'm not real interested in sending a bunch of mail stuff out, anyone want to make an offer for the new stuff as one package? You pay shipping. Same deal on the tubes.

I also have a partial used TR4 carcass, cabinets are sold , and a complete set of tubes (some new some used) for an R4

OH YES !
1 used 6JB6 (sylvania) along with two 6KM6's - GE's (that's how one TR4 came in...working too!)

Thank you Jim for your insights. The plate choke was the first thing I checked for continuity. Just an ohm or 2 resistance if memory serves. While I was in there I cleaned up silver connections at the top mounting screw and the high-voltage interlock to eliminate any possible problems there.

Copy that Jim. I'm pretty sure if the high voltage interlock was "called to action" it would have functioned properly... but the two contact points to ground did need cleaning however.

Jim -

This is really a good idea. At first opportunity I will check this. I think the idling current is lower than 200 mills... (L4B keyed with no input.) I want to say it's more like 100ma but I will check this.

Tnx Jim.

I'll follow the high-voltage line from the input to the anode & make sure
all those connections are good.

Call Tom at Hayseed Hamfest (google it) and he can provide new can electrolytics that drop right in to replace those black cans. He can also provide a complete cap replacement kit for this caps that would be suspect...if you want.
Easy to deal with...good products...and I am in no way affiliated with Tom at Hayseed Hamfest, other than being a multiple-user satisfied customer.

Michael -

I think you are correct on the low IDLE (relay closed, no drive) PLATE current.

Another consideration here is the brand of PA tube. Hopefully you have switched down to CW now
to lessen the strain on everything. With the CW HV (about 1800 VDC):

The "NOS" Amperex brand 3-500Z tubes draw about 100 mA per pair at idle.

"NEW" Amperex brand (China) 3-500Z tubes draw about 170 mA per pair at idle.

Eimac 3-500Z brand 3-500Z tubes draw about 170 mA per pair at idle.

Lane -

Replace all the electrolytic capacitors. These are the ones with polarity indicated on them.

The other epoxy filled caps (black, white or yellow) are high quality film type capacitors and
do NOT require replacement as a matter of course.

Mike

A common fault which could account for both a high apparent grid current reading and low idling current would be increased resistance in the cathode return to ground. A higher resistance here increases the negative bias on the grid, thus reducing idling current. Also this resistance incorporates the shunt for the grid current meter. If the resistance goes up, so does the grid meter reading.

Check R8 and confirm it measures 1 ohm.

Check voltage from cathode to ground when idling and see if there is only 1 ohm resistance to ground.

I used hayseed hamfest for the basic electrolytics package.

http://hayseedhamfest.com/cartlist.html?cat=5
http://hayseedhamfest.com/cartlist.html?cat=5

I used mouser for the non-polarized caps and precision carbon film resistors.

As you've probably seen, get the CD from Gary, K4OAH on the version of the R-4A you have (11 vs 13 tube) as it is really a benefit when doing a restoration.

Note that the big electrolytic can will require removal of the PTO because you are going to need to get a BIG soldering iron in there to get at the old one that's soldered in.

Good luck and if your R-4A turns out as nice as the one I restored you are in for a LOT of hours of great listening.

By the way, I have an article on my restoration coming out in ER in the next month or two.

If you're doing a refurb, consider replacing the electrolytics.

Hayseed Hamfest has kits that include the smaller electrolytics for a modest $4 over the price of the cans alone. It's worth it for the convenience!

Bill -

OK. Please leave old messages intact. I have five of these 'projects' going at the moment, and
it helps me keep them straight.

I think your S-Meter is just hanging around S-2 regardless. Pull the lead closest to the left
side of the chassis off of the meter, (DO NOT unscrew the terminal, unsolder the wire,) and measure the resistance with your ohmmeter. Should read about 200 ohms. Check resistor R13A up
on the meter slide switch. Check it's resistance with your meter as well. While you have the
meter lead disconnected measure the voltage between the center lug of the meter switch, (the one
R13A is soldered to,) and the meter wire you removed.

I believe you checked the DC voltages on V11, 13 and 17, and they were within reason. Check the voltage on Pin 1 of V11 at both ends of the RF GAIN control rotation.

You may have a bad meter.

Hello to the group,

For those of you who use that TR5 you have.

EG; For cw full output on my gain knob is about 9:30, that's a whopping 93 indicated Watts btw, percolating nicely.

In any case if you are using for SSB is my question.

Where is your TR5's mic gain based on a clock at the (by the book) ALC action 2-4 S units on the meter?
Or just where are you running the gain knob? AND What..generally... is your indicated output wattage?

I know that most of us use non peak watt meters.

For those of you who are used to a TR7...no such nicety... on a TR5 its the same knob, stacked pots for CW & MIc gain.
Thank you in advance. Obviously I think I have a problem.

Al,
Wish you had the skirts. Looks like those are impossible to find.

Thanks,

Lawrence

Lawrence
Suggest going through ebay for 4 line parts, and contacting the scrappers
direct and asking.

Wait for Dayton Hamvention in two weeks.

20693. tr7dude?

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-03 20:25:23 UTC
From: geoffrey mendelson
Topic: 20693 Message: 20693

Does anyone have the email address of tr7dude on eBay?

I ordered some components from him and the package cleared customs last week. Unfortunately it was in Luxembourg. I am in Israel.

I sent him an eBay message, but it may not get there.

I hope if he complains at his post office, they may be able to do something, if something needs to be done.

TIA.

Geoff.

20694. Funny ac-4 smell

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-03 23:22:41 UTC
From: Daniel Broniatowski
Topic: 20694 Message: 20694

Hi gang,

I was using my Drake T4xb today and tuned it up without a problem. Strangely, the mic was clipping (transmitting) a bit but I thought nothing of it because in the past, I occasionally had this problem and I think it had to do with two of the contacts squashed together in the mic plug. Yet, every time I would rotate the plug a bit in the jack, the problem would go away and when I opened it, I never found a short. So, I put the plug back together and then used the rig for many months problem free (no clipping) and didn't touch it.

Anyway, I called CQ with SWR 1.3:1 and after depressing the mic, I hear a moderate buzz through the R4b and the S meter was deflected around s5. The power supply was then emitting a smell akin to when I blew up a dummy load last year. I immediately turned off the transmitter and the buzz went away.

Did I blow up something somehow?

S5 is not normal in the receiver, if it's muted. The whole scenario is likely coincidental, but your problem may likely be in the receiver and not the transmitter.

No amount of skullduggery in the microphone could cause the transmitter or receiver to smoke.

You have old radios, and something went "pfffffft!" Given the S-5 description, check the receiver first.

Thanks for the advice Stew. How can you be sure this would solve the problem permenantly (or for the forseable future)? How can I be sure the supply won't blow again? Could the radio have caused any of this?

Best,
Daniel

>73,

I agree with the others that its probably the AC-4. Disconnect the power supply and disconnect the receiver from the transmitter, does the receiver work properly as a stand alone?
Open the AC-4 and use you nose to find where the odor is coming from. May be a bad capacitor, if so you will likely see the residue around it. Caps often have an ammonia odor or a fish odor. Resistors usually have the familiar iodine odor of Bakelite. If its a transformer it more likely has a burning wax odor. Anyway, my may be able to localize it. There are a couple of kits being sold for rebuilding the AC-4. I have experience with the older one. Either is a good idea because if one part has given up others are likely not far behind. I can't explain the S-meter reading on the receiver if it was in external mute, that's why I suggest testing the receiver.
As far as the mic jack, its possible for corrosion of a contact to cause some rectification. I've encountered this effect a few times but usually on headphones. Check this stuff out and let us know what you find.

I can't think of any way the receiver could have damaged the transmitter power supply.

Well, you end up putting all new caps, diodes, and a resistor or two. It wouldn't fix the problem if the power transformer was bad but that's not likely.

Dan,
Yes, it is highly likely that you cooked something in the AC-4. I just spent this morning, installing one of Electronic Specialties ES4AC-4 kits, as I have done now, three previous times. I have had, and installed, both it, and the older, more well known AC-4R kit, from Mike, at the Heathkit Shop. While both are fine kits, my opinion is hands down, the ES4AC-4, is the easier, more readily user serviceable, installation. They both get the job done, and done well, if installed correctly. But, from my experience, the Heathkit Shop's AC-4R kit, is not quite as universal. Drake used different transformers, with different sized bolts, and the AC-4R, to the best of my knowledge, only comes with the most popular sized hardware, to install to the transformer. Not that it can't be modified easily, to fit any, but the ES4AC-4, fits any AC-4, regardless of the components Drake used. And, the ES4AC-4 is a little less costly, and more user friendly, for installation. Again, it is my preference, based on my opinion. Others, may disagree.
Some like Windows, some like Apple. Some like Ford, some like Chevy.
All that said, either will do the job for you, if the transformer, in your AC-4 didn't cook.
As for the receiver and transmitter issues, I think you have two other problems, one each, in each of those two pieces. I'd start with the AC-4, then work on checking if the receiver works well, as a stand-alone. Lastly, the easiest to fix, will probably be getting the mic plug issue resolved. A little De-OxIt, will probably cure that.

If you like to use Drake transmitters, I think you will want an AC4 that you can really trust. So you need new caps, resistors, and (probably) new diodes. Just but a re-build kit. They are GREAT. Once your AC4 is fixed you can worry about the TX. The RX is another beast.

From: <aei_01033@...>
Topic: 20448 Message: 20706

OK Garey

Think I figured out how to include all the old messages for reference.

Resistance across S-meter reads only about 5 ohms with one lead removed. (p.s. I happen to have another used EICO meter - same style, Model 13 ?? - its movement reads 900 ohms. So I tried it in the TR4C.....on power up, this meter floated past full scale and stayed there.) Could not zero this meter.

R13A reads 26 ohms with the meter lead still disconnected.

Voltage on pin 1 of V11 is -0.80 vdc with RF gain full CW and -11.8 +/- with gain CCW. Apparently, that tube is responding OK ??

Only goofy voltage was pin 6 on V17 (the infamous 6AQ5).....I read 218, spec is 155.....

FYI .....this radio is actually a TR4Cw.....not the RIT version though.....

Thanks
Bill

Daniel et al
I wanted to qualify that I certainly didn't mean you caused the power supply problem in any way as some may have taken it that way.

It was purely bad karma and bad electrons meeting old parts. It happens with electronics old and new but particularly old.

A few years ago after a long run of good luck and thinking that some old gear would be a survivor if it was brought up slowly and carefully and babied along I changed my mind on the subject. Too many "it was working last time I used it" auction purchases I guess. I recently acquired such an AC-4. It worked, about 10 minutes, and then a capacitor blew and the smoke rolled out. Fortunately I was right there to pull the plug before serious harm came to the supply or the TR-4C. Normally I would have rebuilt it immediately on acquiring it but I wanted to take some measurements on a stock unit prior to modifications. Never got that far.

That is why I produced the AC-4 rebuild kit as I did. I wanted a reliable product that represented good value, was super easy to install by most anyone with basic soldering skill and the ability to match colors.

I am always amazed after installing one of the kits or rebuilding any old power supply how they all run cooler and quieter and I can leave them un-attended without fear of consequences.

Bill -

OK. You have a bad meter. Your substitute meter is TOO sensitive. Should read about 200 ohms.

Meters show up from time to time on eBay, but a want on the list will probably produce one faster and at a better price.

The V11 voltage is behaving normally.

The V17 Screen voltage is an error on the Drake Voltage list. Yours is correct.

Daniel -

You most likely have two separate problems.

The receiver probably has a bad electrolytic, with the BIAS one(C91) the most suspect.

All these electrolytic capacitors have exceeded their expected lifetime by a couple of decades
and should be replaced. Several have suggested the kits available from a couple of list members
for the AC-4. The receiver electrolytics are available in a kit from <hayseedhamfest.com>.

All are highly recommended!

Grant -

These sorts of mods keep cropping up, too bad Drake couldn't hire some of these 'engineers'!
:-) Strangely, all these 'improvements' rarely come with any useful measurement data. My bike
always sounded better with a couple of playing cards being flapped by the spokes! :-)

Messing with the gain distribution in a well designed receiver is hardly ever a good idea. When
a receiver is sensitive enough that the background noise on a quiet band goes up when you connect an antenna, that's about as good as it gets.

Changing IF gain is unlikely to 'improve' AVC action, since it already has a 60 dB+ dynamic range. The S-Meter might peak higher, unless you recalibrate it.

Everybody wants their receivers to sound like a 1960's hi-fi rather than a communications receiver. Extending the low frequency response doesn't really hurt anything, but it does expose
any hum that may be present.

Tweechies own..... It's your receiver and you can do whatever you want to it!!

Date: 2014-05-04 03:45:07 UTC
From: Paul Christensen
Topic: 20707 Message: 20713

I saw these mods when converting my R4B but really did not want to alter the RF/IF gain distribution. Even my change to all 6V tubes resulted in identical RF/IF performance.

However, I did slow down the fast AGC setting. Apart from that, my changes largely affect the PS, detector and audio circuits. It is a (gulp) hi-fi result with very little cabinet heat and no noise, buzz nor hum in the headphones.

While I like the changes, I have not published them for fear that too many folks would dig in, get into serious trouble, then not get back to where they started.

20715. R4B hum problem and fix

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-04 07:11:02 UTC
From: Richard Knoppow
Topic: 20715 Message: 20715

Some time ago I began to notice hum on CW signals. It did not seem to be continuous so I thought it might be moduluation hum due to nearby power lines. Eventually it got worse and I realized it had to be the receiver. I checked the power supply but it was fine. Well, I finally noticed that the hum occured only when the noise blanker was turned on. I was fooled for a while because the hum did not appear on the calibrator signal but the noise blanker is turned off when the calibrator is on. Well, it turned out to be a bad 12AX7 tube, probably heater to cathode leak. I substitued a tube from another receiver which cleared it up. Today I got a new tube and replaced it. No hum. I decided to see if the new tube made any change in the effectiveness of the blanker. Not sure but I think it does. I have tried a couple of methods of testing the blanker including Garrey's idea of scraping a file with a wire. That works but is not very controlable. I use a Tektronix pulse generator. This does a pretty good job of mimicing the sort of pulse noise that old type automobile ignition systems made. I think the noise blanker was designed mostly with this kind of noise in mind. Well, it works very well. I tested both to see what happened to the s-meter reading and also how much effect the noise had on fairly weak signals. The effectiveness on the AVC level seems to depend partly on the AVC speed. In slow the efffect is very considerable, in fast, the AVC seems to follow the pulse and reduce the effectiveness of the blanker. With no signal in the background the pulse generator runs the AVC up to about 15db over S-9, turning on the blanker knocks it down to about s-4. There is still some noise there but much less. In manual RF gain the noise goes from being quite loud to rather faint. When the AVC is in fast the meter jumps around and the effect trough the speaker seems to indicate that the AVC is trying to compensate for the action of the blanker. On weak signals the blanker will make a signal that is almost completely wiped out by the pulse quite readable, its a significant difference. I tried this on both SSB and CW signals and got very similar results.
The blanker does not work on the familiar frying noise that is so common in the city. I think it works best on short, high amplitude pulses with short rise and fall times and is deaf to signals on the same order of amplitude as the signal. Pulse noise can desensitize a receiver by dominating the AVC and I think the blanker was meant mostly to remove this sort of noise.

The type of blanker used in the R4B is similar in principle to that used in the Hallicrafters SX-28 but there is a very large difference in the way its applied. In the SX-28 the blanker follows the IF filtering, in the R4B it preceeds the tunable filter. This is important because the narrower the bandwidth where the blanker operates the more the pulses will be stretched and lowered in amplitude. This is just was is NOT wanted, the blanker must see the pulse in its full glory and apply its blanking signal where the bandwidth is wide enough not to stretch it. The blanker in the SX-28 reputedly never worked very well and a look at the circuit diagram will show why. The concept was correct but the application was not. The one in the R4B is applied correctly and works quite well.
I can not think of a way to duplicate the noise produced by lighening storms. This is usually a non-periodic crashing noise, probably of very wide bandwidth. However, it can have quite high amplitude especially if the storm is close. Standard diode clipper limiters have the same trouble with this that they do with other noise, namely that if set to knock it down reasonably they begin to produce a lot of distortion on AM and are just not effective when the BFO is on. I think when we had the last thunder storm locally the blanker was already on the fritz so I don't know if it works on this kind of noise.

20718. Drake 2B low signals

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-04 14:37:54 UTC
From: <fasan5@...>
Topic: 20718 Message: 20718

From a silent key I got the radio I was dreaming of in the sixties when I was a teenager – the legendary Drake 2B. After a long sleep it dust and dirt it came alive when I had cleaned the switches and replaced some of the tubes (V1-V3) and the 40 meter x-tal.

It is now loud and clear on 40 meters peaking S9+10 with the calibrator on, and the audio is absolutely wonderful. But on 80 and 20 meters signals are much lower. With the calibrator on I have S7 on 80 meters and S6 meters on 20 meters. However, the signals on these two bands sound stronger than the S-meter readings suggest. Gassy tube or an AVC issue?

With a VTM connected to the AVC plug on the rear I have adjusted the AVC voltage to – 1.5 VDC. With the RF gain turned fully CCW, the AVC voltage increases to -12 VDC. I have tweaked coils L1 and L3 to maximum on 80, 40 and 20 meters. Again using the calibrator signal I have tweaked T1 and T2 to maximum.

The preselector can be tweaked to maximum on 80, 40 and 20 meters, so apparently it is not a preselector issue. What may give an idea of where to look is the fact that on 40 meters SSB the passband control must be tweaked 180 degrees from its position on 80 and 40 meters to catch the right sideband (LSB).

Any advice will be appreciated.

Richard -

My test method was never intended as an evaluation method, merely a way of telling if the Blanker is working or not. It's a pretty stable circuit, and it either works, or it doesn't.!
The TEK generator is a far more 'refined' way of testing, and can give you 'real' numbers to
work with. My TEK pulse generator is a 181, so the piece of wire is much easier to handle.!!

The effect is MUCH easier to see in FAST AVC, or even NO AVC. The Blanker is punching holes in
the signal, and the AVC increases the gain to try and bring it back up!

Peter -

First, keep in mind that the 2-B is an 80M receiver with a crystal controlled converter in front
of it for the other bands. It's unusual that it would work better on 40M than on 80M! This would indicate dirty switch contacts as primary suspects.

You don't mention what meter you used to set the -1.5 V AVC threshold, but unless it is a VTVM
or a 'good' DMM with an input impedance of 11M or better.... The 'fully CCW' RF GAIN setting
should produce more like -18 VDC, indicating the meter is loading the circuit. Even with an 11M
meter, the procedure in the next to last paragraph of the TROUBLESHOOTING section of the manual
is recommended. The threshold adjustment should be -1.35 VDC.......

Replace V2 with a 6EA8.

The Passband Tuner has been mis-aligned. Someone may have just put the knob on incorrectly. Check by rotating through it's full range while watching the four slugs at the rear of the tuner. When the four slugs are fully extended, the knob should be pointing to the right or '3
o'clock'. If it's not, remove the knob and examine the fiber reducer inside the knob. It is slit along it's length, and this slit MUST be at right angles ''90 degrees' from the set screw.
If this doesn't resolve the PASSBAND problem, you may need to realign the tuner. Also, be sure
the 405 kHz and 50 kHz oscillators are exactly on frequency.

Whoa, what a week!

12 hour shifts seven days a week. They're going to kill this old man.

Finally got around to digging back into the R4A with the fubar BFO.

Now, let me back up. Last sunday I called Jeff *Covelli on a un-related issue. In passing, I mentioned if he had the missing T11 transformer as I could not get the BFO to work.*

Told him I had good voltages on the transistor and replaced the suspect capacitors and even mentioned that I didn't feel they were the problem.

*He told he, he'd bet it didn't work. *

Of course I said yes, still no joy.

So... the fix?

Jeff said to add a 10 to 47 mfd capacitor from the wire that goes from the mode wafer to the T11 transformer.

I did. I used a 22 uf at 160 volts (yes, the line is only 12, but I had this one in stock)

Now, I have 16 v pp on the oscillator and the receiver is now working.

I don't know why it worked, or why is even should had worked.

But it did.

That took care of the R4A.

Now. I decided to dig into my fubar TR4.

As I said the file and wire method works and will test
if the blanker works. I wanted something more repeatable
and tried a pulse generator using a bug and inductance, that
produced something close to ignition noise. When I got the
pulse generator I tried it and found it would give me a
good, repeatable test. Plus, because the pulse width and rep
rate are easily changed, it would give some idea of what
sort of signals the blanker works on. I found that the
effect is very obvious in manual RF gain, there it makes the
noise virtually disappear. In fast AVC you can see the
difference but the AVC tends to follow the residual pulses.
On slow AVC its again very obvious. Checks on actual
signals show that the blanker will make signals that are
completely blanketed by noise quite readable.
I think if you are used to the conventional diode type
noise clipper the noise blanker may be disappointing because
it does not do much for the usual frying power line noise,
but it does work and the diode limiters do not really do
much except to reduce noise in the absence of a signal. They

are useless on CW. These days I rarely ever hear ignition noise but it was once very common and a bane especially on the higher bands.
I don't really know how long that tube has been bad but I think for quite a while. The hum was not very bad but was noticeable on CW. Probably on SSB too but perhaps my hearing problem masked it. I am happy that I finally figured it out. I will check this tube later on my TV-7 and see if the problem shows up on it. I remember testing all the tubes in the past and not finding anything so it may be one of those problems tube testers don't show.
The R4B is really a remarkable receiver and has all the features one needs. I was listening to the contest last night and found that the combination of the pass band tuner and notch filter would pull out nearly anything. What a lot of performance Drake managed to pack into that little box.

Yes, that makes it clear. Its important to isolate the
problem and to make sure there are not two problems masking
each other. The most likely cause, as has been pointed out
a couple of times, is the power supply. While there may be
only one bad cap in it all are old so the best solution is
to replace all with a kit. The kits also have other
components which are subject to ageing. Once done the supply
will be good for a couple of decades.

20726. Cable info for 7 line

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-04 19:10:19 UTC
From: Paolo Emanuelli IK1QHB
Topic: 20726 Message: 20726

Good evening folks

I wanted to ask a question to the more experienced:

the connection cables between the tr7 and r7 leaving the cable accessories that kind should it be?
I am referring to the two wires that go from the socket "external antenna" and the "external receiver" from tr7, to the "external receiver" and "main" in the r-7 ...
Coaxial cables with 52 or other impedence are required, or just use shielded cables?
Can i use .... random lengths, or lengths calibrated as in the lines c and b?
The cable accessories ... must be cut to length calculated or random?

Many thanks to all

Paul IK1QHB

Hi Garey,

Following your instruction the passband problem is now solved , and the AVC threshold voltage is now - 1.35 VDC on a VTVM. RF GAIN still produces no more than - 12 VDC. A 6EA8 to replace the 6U8 (V2) has been ordered and will arrrive in a few days. The 405 kHz and 50 kHz oscillators will be checked in my local radio club.

20732. T4X-B PA won't tune

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-04 22:37:34 UTC
From: Brian and Beth Miller
Topic: 20732 Message: 20732

Operating on 20m lately I noticed that the plate current dip did not correspond to maximum output power; it was just a little off so

I decided to tweak the neutralization on my T4x-B. I performed the adjustment as per the instruction manual. I subsequently checked it at 20m where it was fine. I didn't do anything after that other than to lift the chassis off its side (it was on its side so that I could access C49) and lay it flat on my workbench. When I turned it on again something was wrong; I can no longer get a plate current dip when adjusting the PLATE control. I can successfully tune (peak) RF TUNE, but there is no longer a current dip when I adjust PLATE. Maximum output power occurs with both PLATE and LOAD set maximum clockwise. I tried DeOxit on the 2 band switch wafers in the PA compartment to no avail. Has anyone seen this before?

I don't have a specific answer but it sounds like
something may have come loose or even fallen into the rig.
Do you by any chance have a grid dip meter, if so you can
use it to check the resonance, or lack of it, in the plate
tank circuit with the power off.
Another thought, check the neutralization cap for a
short.

I don't think it's critical. I used ordinary RG-58A/u for the antenna cables. For the control cable between the radios I used some low-capacitance 90 Ohm Teflon mini-coax that I had on hand for the RF connections, but others have used RG-174. I made it the same length as the Drake control cable. The audio patch cable can be anything, shielded is probably a good idea.

Subject: [DrakeRadio] R4B hum problem and fix

I tested the hummy 12AX7A in two tube testers, a TV-7D/U
and a Weston 981 Type-3. The tube tests good on both
testers. No indication of a shorts or leakage and Gm is
above the minimum. The Gm is also exactly the same in both
sections. Yet the tube hums. Well, tube testers will spot
really bad tubes but not always marginal ones. This tube
may well work in some other circuit so I marked it and will
put in my stash of spares. I think tube testers are
valuable but the final test is whether the tube works in a
particular circuit regardless of what the tester reports.

From: <clwelsch@...>
Topic: 12987 Message: 20736

Hello Garey,

I have been absent from the Drakes for some days as I had other work to do...

I got all the TR-4C CD information into my folder. Thanks for this transfer.

But my problem on 80m remains. A new capacitor at C145B didn't change anything and adjusting the VOX and ANTI-VOX controls neither. Where is VOX DELAY?

What and where are the keyed Cathodes (XMIT K)?

There seems something dying slowly in there but I don't yet know what? Could it be a tube? Remember it is only happening on 80m (all other bands being correct) and now the plate current is immediately up to 600 mA as soon as I hit CW for tuning. I don't even wait for it to go down anymore so I don't know what's the periodicity now.
Output power is ok when it is properly tuned and low or nothing when it's out of tune but plate current is always 600 mA. It is also 600 mA when the SIDEBAND switch is not at X!

Greetings

Claude

Claude -

OK. I may need a refresher on your problem. I've done about a dozen different 'projects' since
then!! :-)

There is no VOX DELAY control. Delay is determined by a 'select at test' resistor (R106), nominally 3.3M.

Did you replace C145, or just add a cap across C145B? If the latter, did you disconnect the terminal from C145B?

Can you set the IDLE current to 100 mA?

I'm suspicious of a bad connection or switch terminal (S1-G) in the Pi Net output area, allowing
the PA to oscillate at 'some' frequency. 600 mA is bad news for PA tubes. If you have a Grid
Dip meter, it might be instructive to check resonance on 80M. It's also possible to inject a
signal into one of the terminals on the side of the LOAD capacitor and scope the rotor terminal
of the PLATE capacitor across a 1500-2000 ohm resistor to ground. Adjust caps for resonance,
max signal at scope.

The XMIT K line connects the Cathodes of V4, V6 and V15 to ground them to enable TRANSMIT when
the relay is closed.

From what I remember Garey told me, when the LOAD control is turned up and up and up and output STILL is increasing (into a dummy load) that is a sign that your finals are oscillating. Are you sure nothing on your final tubes was knocked loose? Are those resistors (parasitic suppressors?) on top still attached well? I think this all has SOMETHING to do with your finals, since that is what you were mucking around with.

Topic: 20499 Message: 20739

Hello Stu and to all in this long thread,

R8 is good. One of the first things I did was check the resistance of R8 when the T/R really close, so I measured it from the center tap of the filament transformer as I closed the relay. Removing the +120 volts from the cathode and putting the grids to ground through R8 keys the L4B normally with appropriate grid current.

I'm stumped right now and am going to give it a little rest.

I so much appreciate everyone's participation and help with this most perplexing problem. Till later... 73,

Mike AA7WM

Hello Garey,

The problem was that the transmitter of my TR-4C works fine on all bands except 80m. On the 80m when I tuned with CW, plate current oscillated between 100 mA and 600 mA with no drive, with a period of roughly 1 sec. Meanwhile as soon as I turn to CW, plate current goes to 600 mA. As I switch back immediately, I won't know what the period now is. When I tested with a new C145B capacitor, I had the one in the can disconnected.
It also happens when the sideband switch is not on X, where normally on the other bands I cannot tune. It happened with all positions of LOAD, TUNE and other controls, but the real output power of approx. 100 W is only there when TUNE and LOAD are right.

And this problem started only after I did the 5-14 adjustments in the manual. I don't know if there is a relation, but before 80m transmission was fine.

Frank Krize, K5SVC (k5svc@...) has the best tubes, at the best prices, I've found, and he's a great guy to deal with. Almost all are mil-spec NOS. And, as many as I have purchased from him, I've never gotten a bad, or weak tube. I've probably bought 100-150 tubes from him, and still have 40, or 50 in my current supply.

Dan,
Last time I emailed Frank Krize about Drake tubes, he was only selling complete sets, no singles of the hard to get ones like the 6HS6's. Of course it never hurts to ask, but that was the response I got. His tubes ARE great, however.

Butch -

Try ESRC at <http://www.esrcvacuumtubes.com/>. Good tubes, good prices.

Be sure and get several 12BA6s. They are the most problematic, grid emission.

Sometimes the 6EH5 is trouble. The rest not so much.

What's rarer than W1AW/0 Nebraska?

How about W1AW/0 NE running on vintage Drake gear!

I'm scheduled for 17 Meter digital modes this week from my home shack. I'll be running the 7-Line with my NCL-2000. Probably mostly RTTY, but I'm going to try to work in some PSK.

I'm running the NCL-2000 instead of the L-7 because it presents a nice 50-Ohm resistive load to the TR-7 on 17 Meters. The L-7 will be standing by should the aging caps in the NCL blow chunks.

My shift will be 2100-2300 UTC, on or near 18103. That's 4-6 PM CDT, weekdays starting Wed. through next Tues. Satuday I'm scheduled for 1800-2100 UTC, and Sunday 1300-1500 UTC. If you hear a signal outside of those times, it's not me.

Full schedule is here:

http://k0ha.com/w1aw/w1aw.htm

Each date has it's own chart, clickable at the top. Where you see a letter in a square, that is a code for the op. I'm "C", go figure...

I'll also be working evening shifts from K0GND on 20 fone, but that's only a Yaesu....

Hope to hear you on the air!

Hi all,

Well, a TR-4C/AC-4/MN-4 followed me home from the Sandwich hamfest this weekend. Seller said the meter pegs when turned on, and otherwise seemed deaf and mute. Really wished it had the noise blanker, (I NEED one for use in my vintage mobile setup, you know, breaker point ignition and all..), but waddya gonna do.. The price was right at a C note for everything.

Spent a few minutes checking it out tonight. #1, I turned the RF gain control fully CW, thus fixing the pegged meter "problem."

RX was dead, but could hear the calibrator with the volume at max. Pulled the bottom cover, taa-daa the #12 fuse lamp was black and open. Stuck a new one in place, and immediately heard some 20m digi. The AF gain pot is screwed though, it's open unless turned nearly full CW.

TX doesn't engage so it still has other issues, but it WANTS to work- so it's worth saving.

So- Who has a spare AF gain pot (or the entire AF/RF/AC power switch assembly) they're willing to part with?

If you don't want cash, I will trade for rubber bumpers, #12 lamps, burnisher tools, or anything else in my ePay store if you would prefer. I should also have the *correct* size stud bumpers used on the AC-4 in another month or two. I elected to have them custom made in a long lasting, non-marking EPDM.

Regards,
Chris kc9ieq

Hello Garey,

I checked the XMIT K signal. In receive mode, I have 154 V on this line, in transmit mode (relay closed), I have 4 mV and 12,4 Ohm on this line, Is that normal? Shouldn't it be directly to ground? I've checked the contacts on the relay and they are OK.

I have had a couple bad 6HS6's but not in a while. I had a problem with wicked noise once that was a 12BE6 that looked "fine" on a TV-10 tube tester.

Yes, tube testers are screening devices and don't catch everything. Having said that, I am considering doing a refurb to mine: it still has the 866 rectifier, which I worry about. The thing is useful for screening tubes. I need to replace two of the sockets as well, so this is gonna be a real "project".

There were a few mods on a site (http://www.antiqueairwaves.com/nlee/tv-3&10.html) that re-capped the tester and solid-stated the rectifier. Nolan Lee compiled extensive data on the military tube testers and his pages have been preserved in a few places (he's now an SK). He also compiled extensive "roll chart" spreadsheets) .

Claude -

I don't know that 4 mV is a problem, but yes, it should be a hard ground. If you're in transmit, perhaps you're getting some RF into the meter??

Have you made the 'screwdriver tour' through this radio yet?? The first thing I do with a 'new'
radio is first to verify that the 'correct' fuse is in place in the AC-4, and second is to go
through the entire chassis and put a screwdriver on EVERY screw. Tube socket mounting, terminal
strip, PC boards, shields are all used for ground connections. If loose, tighten. If tight, loosen a quarter turn and re-tighten. Carefully examine solder joints and components as you go.
This procedure will 'solve' a LOT of problems, and save a LOT of troubleshooting.

Steve -

Bad 6HS6's are pretty rare. That is one tough tube!! :-)

Other tubes DO fail, but far and away the 12BA6 and 6EH5 are the most frequent failures, at least in my experience.

That must be SOME tube tester if it has an 866 rectifier!!! :-)

I've always been suspicious of the 83 rectifier used in the TV-7. Mercury vapor rectifiers are
specified for vertical operation ONLY, the the 83 is horizontal unless you put the TV-7 on it's
side. MV's also like to have a period of warm-up before HV is applied to allow the condensed
mercury to vaporize. I guess it's like the bumble-bee!! :-)

20756. Moving on to my fubar TR-4

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-06 15:12:20 UTC
From: <prosolar@...>
Topic: 20756 Message: 20756

Boys and girls,

after returning my R4A back to service, I've opened a spot on the service bench for my ailing TR-4.

There're two issues.

The audio output is low, need the volume control into the stops to hear stations. I thought I had a bad audio transformer, may still be bad, but suspect an other problem.

There is no TX. The T/R relay won't pull in in any position of the mode control.

I suspect the two problems overlap.

The voltages on the 6AQ5 are good

However the voltages on the 6EV7 are no so good.

On pin 6 of the 6EV7, instead of 110 I have 25. Not good. The 100k resistor feeding that pin had changed value to 133K. Replaced with no joy. I suspect the 10 uf cap to be fubar, but haven't found it yet.

There is a .01 cap that couples the audio from the 6AQ5 back to the second half of the 6EV7, as anti-vox. I'm going to lift one lead of that cap and see if my audio comes up to full bore.

Yes, I've tried a new/different 6EV7 and got the same results.

While this isn't a do or die project, it bugs me not having one of my Drake radios not working.

Any ideas before I dig deeper?

20758. Drake Receiver Fuse Rating

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-06 15:41:03 UTC
From: <dj_coffman@...>
Topic: 20758 Message: 20758

Ok all, here is my stupid question for the day; I'm sure this has been discussed numerous time however, I have not found the answer surfing the group.

I have found a fuse rating for the R4B and R4C receivers in the schematic. For some reason, unless I have just overlooked it in the manual, the only place I find the information is in the schematic. The schematics show a requirement of 3/4 amp slow blow. Is this the correct fuse for all versions of the R4B and R4C receivers?

I have an R4 without a manual, what is the fuse requirement for this receiver?

Over the past 6 months, I have acquired 6 Drake receivers (Note Severe addiction or sickness) and am now working slowly to go through them and get them on the air. All of them have come to me with incorrect fuses ranging from 1.5 amp all the way to 5 amp. Luckily nothing has been burned up, but goodness they might as well wrap a double mint gum wrapper around the fuse and stick it in.

Thanks for humoring my stupid questions,

Doug - N9XTF

Doug -

All 4-Line receivers are 0.75A, Slo-Blo, EXCEPT the R-4 that is 0.6A, Slo-Blo....

The AC-3 and AC-4 were originally a 5A Slo-Blo. Drake later said a 6-1/4A Slo-Blo is ok if the
5A blows too often!

My favorite 'fuse' was a piece of #2 solid copper wire, carefully straightened and filed smooth
on either end. Fit perfectly!

Garey,

As usual, thanks for the information. Is this information published in the manuals or just in the schematic?

I used to work for a mom and pop outfit in the concrete block industry; if there was an electrical problem in a piece of equipment, the owner would insert a fuse similar to your description or anything to bypass the fuse and then look for smoke. He also used to use 110V light bulbs to stick in 480 volt panels to test for voltage. I watched him blow a number of them up; it makes a brilliant light and noise that's quite funny if you are not the idiot holding it!

Thanks,

Doug

Garey,
Seriously, when I was service manager at a GE Two-Way Shop, we had a tech that could fix anything in the shortest period of time, especially when anything came in blowing fuses. He had one of your "specialty fuses", would slam it in, turn on the radio and with his hand on the "off" knob, would look for smoke, heat, smell. Usually he found it quickly...and then went to work troubleshooting. I never had the guts to do that!!

The manuals specify Power Requirement at 60W for all models. This is 0.5A at 120 VAC, but we
gotta allow for that 'bright' flash at the turn-on with the 'light-bulb' test fixture.... It
takes longer for the initial cap charge and cold filament surge to finish to cover with just the
'Slo-Blo' time delay.

So you gonna need a R-4A 'combo' CD??

20766. Re: [DrakeRadio] L4B - low output with new tubes.

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-06 16:56:16 UTC
From: Michael Engstrom
Topic: 20499 Message: 20766

Hello all...

Tnx to everyone... Garey, Paul, Jim, Stu, Joe and many others for there help. I am summarized the problem and the actions taken, and for now I'm going to give it a rest.

It's a Drake L4B amplifier with excellent tubes and a good power supply that only puts out about 350 watts on all bands.

Band: Any
Idle plate current, keyed, no drive: 120ma.
Drive: 10 watts from ft1000
Grid current: 220ma
Plate voltage: 2500 under load.
Plate current 250ma. W/ a sharp dip.
Power out: abt 350W. Measured with L4B meter and external watt meter.
SWR <1.5:1. Antenna or dummy load.

Increasing the LOAD only produces less RF output and re-dipping the plate becomes very broad (not sharp).

On 80, 40 and 20 the greatest power output happens when the LOAD control is fully counter-clockwise or maximum capacity. On 15 and 10, I can advance the LOAD a little bit Clock Wise to get peek power, but I don't advance it much.

Plate current dips where it's supposed to as indicated by the RedPointer on the front panel TUNE control.

Input SWR is good. <1.5:1.

&&&& Observations/Actions &&&&

It seems like a lot of grid current for a small amount of drive.

Cleaned all contacts, wafer switches and relay.

Made sure that the input wafer switches and the output tank circuit band switch are synchronized. (There's a plastic chain that keeps them synchronize when turning the BAND switch.)

All the RF Chokes test good... They look good too, no dark or brown spots.

There's Low resistance from anodes to the high-voltage connector. Main RF choke had good continuity, low resistance, just a few ohms.

It seems like the answer rests in the fact that there is so much grid current with so little drive?

When the L4B is keyed, +120 volts is removed from the cathode and the center tap of the filament transformer is grounded through a 1 ohm 10W resistor. Checks okay. Normal idle plate current of 120ma flows and grids pull current with drive.

Its acting like an amplifier the doesn't have any plate voltage or low plate voltage or some resistance in the anode circuit or a high voltage power supply problem. But the high-voltage remains consistent, only changing a couple hundred volts underload which is normal.

Stumped for now.

73,
Mike AA7WM

Maybe it's not an 866. I do know it has a MV rectifier using a 4-pin layout, so assumed an 866.

Yes, and I am concerned about it for that very reason. It's long past time that I rehabbed this old boy: I've owned it for over 28 years - bought it for $25 at the Framingham (MA) hamfest back in the 80's. Still has the price tag on it and I rememeber using it when my shack was in what became my younger (28-yo) son's bedroom. That's where my first C-Line lived, too.

Yeah, it was funny - I had one weak 6HS6 and one with shorts. Replaced them and the receivers worked better afterwards. The weak one is still in a box in case I someday have no alternative. Yes, I also have some 6AH6's and have tried them in place of the 6HS6's just to see if they work. They do, but I'm sure there are some other issues like dynamic range and IMD that could be affected by changing over to them.

I plan on taking some photos when I start digging into the tester. It should be interesting and educational.

Later -

Steve, W1ES/4

Yep got all the rest of them.

Oh I don't think I have one for the tr-6 yet. Probably gonna sell that one though.

Fuse size is something I don't remember seeing covered
in any engineering texts. I did read somewhere that the
usual practice is to fuse for twice the normal demand
current. I don't think that can be a good general rule.
Also, there are several speeds of fuses; common ones are
either fast blow or slow blow but there are extra fast blow
and I think delay fuses too. There are also anti-arc fuses,
I think the ones with springs in them are of this type. Your
fellow with the no.2 wire sounds like the penny in the fuse
box, works fine until the fire department has to come.

I was surprised when I found out my TV-7 has a mercury
vapor rectifier and runs it on its side. Also there is
nothing in the instructions about warming it up. I use the
tester fairly often and have not had a problem. I have
forgotten the tube type in it but at one time there were
many small sized mercury vapor rectifiers such as the 83,
note not the 83-V which is a vacuum tube replacement. I
suspect mercury tubes were used because they have a low
voltage drop that stays constant over a wide current range.
Thats why they are used in transmitter power supplies;
relatively low power dissipation and good regulation. A

silicon rectifier will often replace these. If you stack several of them you can about duplicate the voltage drop of the mercury tube. Most mercury tubes have a constant voltage drop of about 15 volts, a silicon diode about 1.5 volts so ten diodes stacked will give you the same voltage and have even better regulation. This is different than when replacing vacuum tube diodes which do not have a constant voltage drop or constant equivalent resistance. The internal resistance follows the 3 halves power law that is common to vacuum tubes. Anyway, I am going to leave my TV-7 alone until I need to change something.

Brand of PA tubes?? Old Amperex, EIMAC or New (Chinese) Amperex.??

Excessive Grid current isn't the problem, it's a symptom. Loading into a dummy load, with the
LOAD control at minimum, you will see excessive grid current with drive. When you increase the
LOAD clockwise, and power is transferred to the load, the Grid current will drop. If you increase the Drive, the Grid current will increase again, increasing the LOAD further will again
reduce the Grid current.

So the problem is not excessive Grid current, the problem is that the PA is NOT seeing (matched)
to the load, and little power is being transferred. If you take a fully operational amplifier,
and leave the LOAD control at 0 as you increase the drive, you will see this exact behavior.
Your amp acts exactly as I would expect if you DID NOT advance the LOAD control. (Which is why
that was my first question, 'is the LOAD cap turning as you turn the knob!') :-)

serial number is 16998

for whatever reason, when it saw me coming with the test probes in hand, the plate voltage of the 6ev7 is now where it should be.

If I plug in a mic, in ssb mode, I now have VOX operation.

NO CW

it seems like the sidetone is not running and keying the VOX. Don't have time to dig into it deeper today

R103, 115 and C145 are in good shape. I have a strong 250 volts on the supply side of the resistor feeding the plate of the 6ev6

I'm not happy with the self-healing circuit and can't seem to get my mind around why the voltage is now correct when it checked it sunday, it was 24 vdc.

OK. That's a Version 1, practically a TR-3!

CW and SIDETONE are generated in V2, probably the tube. This is what activates the VOX also in CW.

All this discussion of fuses I am passing on a hamfest tip, since Dayton is coming up soon.
Check the fuses and ratings on old gear found at flea markets

If it is blown or way oversized it is a red flag that something may be wrong

That AC4 I recently was testing just to see what condition it was in had a 8 amp fuse in it. The supply ran 10 minutes before a capacitor exploded.

Had I looked at the fuse first I would have been more cautious and went immediately to rebuild

Look for something like dirty tube pins, or bad socket
pins. Tube pins can be cleaned with a toothbrush and
toothpaste or even find still wool if very corroded but if
you use steel wool wash the pins to make sure there are no
metal particles adhering to them. Also, follow Garrey's
advice about working all the screws to make sure they ground
properly. It might also be worth poking and wiggling the
wiring. Its just possible there is a bad solder connection
or even one that was never soldered. Those can be
maddeningly intermittant. Since you got a low voltage

reading at a tube socket I would be more susicious of wiring
than of a tube.

So that's where fusestats came from. Those blasted things were around by at least 1940, they are used in some Rock-Ola jukeboxes of the era. Guess they didn't take off that well, as Edison base plug fuses still greatly outsold fusestats when I left the hardware store a mere 9 years ago.

the Edison base was standard for a long time, but unfortunately it was just 'penny sized'.

So along comes the Gummint, decreeing Fusestats. All the good little citizens were supposed to
hire electricians to come in and thread the little adapters they sold (complete with 'teeth' to
prevent removing the adapter once installed) into our Edison based fuse boxes, thereby protecting us from ourselves...

Some things never change!!

A google search shows Fusestats are still made. This
house had adaptors for Fustats in the fuse box before it was
re-wired with circuit breakers. I think circuit breakers
are required by code now.

I haven't had much time to spend on this project. Working 7 days 12 hr shifts.

I did check all tubes in tester and nothing showed up as being bad.

If I am not too pooped I'll sub in a different one tomorrow.

I am working till 3 am.

Oh, golly, forget the radio and get some sleep while you
can. The radio is not worth the stress plus when you are
more rested you may discover the problem right away. I hope
you are making a fortune off this.

I know nothing about L-4B's. Never even seen one. So by all means tell me to get back inside my soap-box. But I have a thought...

Reading what Garey has said and then glancing at the circuit. It occurred to me:-

How is the LOAD capacitor body connected to electrical Earth? Is it possible that the circuit is seeing a series capacitance between the LOAD capacitor body and Earth? Which prevents the LOAD cap from presenting the correct capacitance value? Loose screws, cracked wire and/or cold solder joint introducing unwanted series capacitance where none should be?

Anyway, just an idea.

73, Steve.

Steve -

Good thought, but the problem as I see it is too MUCH capacitance to ground. 0 on the LOAD cap
is full mesh, plus a few fixed caps switched in on the lower bands. Increasing the LOAD control
reduces the capacitance to ground.

Did the OP ever examine the load capacitor to see if
its doing what the knob says, that is it may be turning but
maximum capacitance may not really be at maximum CCW. I
don't even know if this is mechanically possible. I am also
somewhat suspicious of the band switch section that works
the load capacitors. The broadening of the plate dip is
characteristic of increased loading since the load changes
the Q of the plate tank but the power should be increasing.
If the loading is too much it will cause the output to
become lower. I think the dip stays broad but don't
remember. I think I would examine the whole bandswitching
arrangement including the bead chain to see if its out of
kilter somehow.
If there was too little load I would be suspicious that
one section of the loading cap was not attached at the band
switch.

20797. Anyone got a couple old 4-pin tube bases laying around?

Yahoo group: DrakeRadio (2014-01 — 2014-05)

From: Steve Wedge
Topic: 20797 Message: 20797

With respect to that tube tester I have, I'm planning on replacing the mercury rectifier with some 1N4007's and series resistors. I'd like to do this in a modular fashion by using an old 4-pin tube base. Anyone got a couple of these? I don't have any tubes that old anymore.

Here's a chance to get rid of any you have that are kaput and make a few bucks...

What you have described is a classic Plate Blocking capacitor problem. Try a replacement. After that check continuity through the band switch to assure the correct coil tap selections (as you go higher in freq, it shorts out windings). Also, check the rf choke on the amplifier output line.

Check relay contacts and check that the SO239s socket centers securely hold the PL259 center pins (and check for oxidation). (that occurs more on dummy loads, but the L4 is a few years old).

This is where I start looking with these symptoms.

Good luck.

Tim -

The Plate Blocking capacitor was the second thought. The L-4B uses two 0.001 uF caps in parallel. Not likely both would open up at the same time?? Agree it would be best to sub, but
not easy to hand, and both 'checked' good.

The problem is on all bands, and switch contacts have been checked and verified to be in sync
with the input network switch that is chain driven.

A shorted turn in the output RF choke would make smoke with 350 to 400W that is coming out of
the amp.

100W of drive goes through the amp in standby to the load with minimal reflected power. Input
match is good, shows minimal reflected power on wattmeter between transceiver and amp input.

Sure seems like we have checked and verified 'everything', but apparently not quite!!

I'm looking forward to finding the 'real' problem... "Well, I never thought of THAT!!!" :-)

Gang,

at a quarter to 4 this morning, I fired up the TR4. I thought for sure I had a spare 12AV6, but none were found. I'll have to order one, or wait until dayton for a spare.

the voltages checked within limits on the pins.

before I head to work, I'll scope the circuit and see if the sidetone is running,

Don't do it. The charts were calibrated with a machine using the 83 and 5Y3 rectifiers, and their associated voltage drop curve vs current. Replacing them with anything but, will completely change that curve and totally blow the accuracy of the tester. Many have been here, and many have failed. This was explained to me in great detail by the legendary Wendell E. Hall several years ago before he died.

In normal intermittent service, those two tubes will last pretty much forever. Just spring for another 83 and tweak the calibration if needed.

To follow up- Just read your posts about the TV-10. Why can't I find that kind of stuff at garage sales!

Have you once, EVER heard of the 83 in a tube tester physically blowing? I haven't. Remember on the 82 and 83 we're talking hundreds of volts here, not thousands like would be seen on a 866, 872, etc. It's still best to let them warm up for a few minutes allowing the mercury to fully vaporize, but flash-over is basically a non-issue in this application. Even if an 83 DID flash over or short, I sincerely doubt it would physically break and outgas.

THEN we have the debate about just how toxic mercury really is (or isn't).. Let's leave that one for another forum :)

My .02 in a nutshell? If that 83 hasn't given you any trouble in the last 28 years you've owned it, it's not going to now. Can't hurt to pull it out and check in another tester, but I'll bet it's just fine.

Regards,
Chris

Assuming, as you state, that everything checks-out, I would remove the tubes, connect a 3k or something close from one anode connector to ground and use a dip meter to see if the final tank resonates somewhere near the correct posiitons of the capacitors. This is not an exact value, but it should result in resonable readings.

Is it possible the plate choke is damaged (shorted turns) or the bypass cap at the HV connection to the plate choke is open?

Either of these will cause "tuning" issues at the anode circuit.

Tim -

That was my last suggestion! I said terminate the input to the pi-net with a resistor and then
poke a signal generator in the OUTPUT connector. Scope across the resistor and go. Seems strange to say, but today a lot more people have signal generators than grid-dip meters!! :-)

The PLATE choke has been examined (single layer) and at these levels a shorted turn would be
pretty obvious pretty quickly! I, or someone else suggested the decoupling cap, and it was reported as ok. I don't think that would kill it to this state if open. A short would be easy
to spot!

It's really a stumper...

20811. Setting plate bias current

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-08 23:25:13 UTC
From: Brian and Beth Miller
Topic: 20811 Message: 20811

There has been a lot of traffic on this subject lately and I should have been paying more attention. But all the fuss about bias current got me to question the setting on my TX4-B, so since I had the covers off to align the transmitter I thought I would check the plate bias. This is what I did:

-Using a precision multimeter I measured the resistance of R36. The color code indicated 3.3 ohms, I measured 3.77 ohms

-Based on the schematic, I conclude that virtually all the plate current flows through R36 because its resistance is so much smaller than the circuitry which shunts it: primarily R38 and the meter.

-I calculated 70ma * 3.77ohms = 0.264V.

-I placed the multimeter probes across R36 and tweaked the bias adjust for 0.264V across R36.

Is this correct? I ask primarily because the meter indicated over 100ma when I was finished with this procedure, so I'm a little suspicious that I messed up.

It all looks good to me, I just got my T-4XB in the mail today so I may be the last person you should listen to. If you are good with your measurements to this point you now need to change the resistor on the meter switch to get your meter to show the proper setting. Thats R38 on my print and is mounted on the slide switch up front and on top.

Hello Dave

Well I'm just learning this radio to so I will put this out and I'm sure the pro will chime in and say im off lol .... first if your radio meeter is working correctly you should adjust your bias to the line this is the line on top of the scale in the middle of .0 and .1 turn the rf gain pot fully ccw and place the radio in tune to properly adjust the bias.

Under the radio were the two 6jb6 tubes are you will see a copper flat bus Barr with your DVM you should get -70vdc give or take. If you do and your needle is way off then we can move on to the next test.

Dave

Brian -

You got it right so far! Once you're satisfied that the current is correct, which it appears to
be according to your measurements, you need to change R38, the resistor on the slide switch behind the meter 'button' between the TUNE and LOAD controls. That is a select at test resistor
and pick the closest one to read 70 mA on the panel meter, right side up.

R36 is not really a 'shunt' in the common use of the term. It's merely a resistor in series with
the Cathode line of the PA. The meter and R38 are a DC voltmeter that measures the voltage drop
across R36. What has happened to your transmitter happens to a lot of them, R36 has aged up in
value, increasing the voltage drop across it for a given current. This makes the panel meter
read 'high' as you discovered, which causes the operator to increase the BIAS beyond the design
goal, changing the operating point of the PA, (toward Class C,) and out of its most linear region.

Hi All,

After a lot of thinking, I have decided to sell my later
serial number & nice R-4C, $250 + shipping. Contacted me off
list if interested.

73,

Bill, WA6NEQ

Very good. Makes sense.

I think I may have a good spare around in the shack somewhere.

I'll keep an eye out for another as well.

Tnx for your assistance as always.

As Garrey mentioned R-36 changes value with time. Also, if memory serves me, two different values, 2.7 ohms and 3.3 ohms were used because two different meters were used. I am going by memory but I believe one meter is calibrated to 400 ma and the other to 500 ma, the higher value resistor goes with the higher scale meter.
The best place to measure the plate current, actually cathode current, is at the 15 ohm resistors at the cathodes of the tubes. Make sure these are really 15 ohms because they also tend to drift with age. If they are not 15 ohms replace them. Garrey recommends metal oxide film resistors. When they are the right value each tube should measure 0.525 volts across the resistor. That, of course, is 35ma. They may not be the same due to differences in the tubes. You can measure the voltage on each and add the equivalent current to get the total. You can set the bias to get 35 ma per tube. The series current sensing resistor at the meter i.e. the 3.3 or 2.7 ohm resistor should be the right value. The meter trimming resistor, R-38, should be adjusted so that the meter reads exactly 70 ma. If modern resistors are used you will probably never have to do it again. Getting the current meter calibrated is very important because the circuit is designed to have minimum distortion at the specified idling current. Operating at the wrong bias will increase distortion and may affect tube life.
One more thing, a cooling fan will extend the tube life. Many of us have used small muffin type fans fixed with some weather stipping or small rubber feet and just set on top of the transformer right over the finals. The fan should blow OUT so that cool air is brought in around the tubes. Blowing IN blows hot air over the chassis. I use 220 volt fan on the 115V line. It runs slowly enough so that its silent but still draws enough air through to keep everything cool.
The T4XB is a very satisfactory little transmitter. It justifies some work because it has very good performance.

Guys,

I had to do it. I took a me day off work. All those 12 hr shifts were slowly killing me.

So, spent some quality time with the TR4 that has been giving me issues.

Lacking a different 12AV6, I pulled the old one back in. No joy. Walked away and mowed the grass. Came back, and whoa! Sidetone and the relays click in in the "X" position.

Audio still seems low. I have to run the volume control at full bore for normal listening volume. I have 22 vpp on the input to the 6AQ6. Different tube, same problem.

The VOX snaps on and off with the volume control level. The anti-vox helps, but sill not right.

Can't hear squat on 20 meters except for loud stations. (see below)

Sometimes putting a finger or two around the 12AV6 causes a noticeable squeal.

And speaking of which, depending on the position of the VOX gain control, I can hear a high pitched squeal in the receiver's audio. Find the correct spot on the VOX gain control and the squeal goes bye-bye.

80 meter RF output is low, about 50ish watts.

Just for grins, I didn't fire up the big guns, but used a elecraft signal generator and tweaked the IF and 80/20 mixer transformers. Before I couldn't hear a 1 uv signal, but now i can. It was quick and dirty.

The chassis is in bad shape, complete with green stuff growing on it. Front panel is okay, so I don't know. I do know I can't save 'em all and this one is at the border of becoming a parts pig.

And one last item...

How in the hell do you get that red knob that slides the calibration plastic out without taking the whole front panel apart?

Best kind of problem there is!!! :-)
>
>

The TR-4 is known for low audio, but not that low. Drake added a single transistor preamp in
the "C". 22 V p-p is enough to drive the 6AQ5 into clipping. The Grid is only biased about 10V above ground! Have to look at the obvious. Bad speaker or cable? C135 is the obvious next
suspect. Then C136, C142 leaky. Rest of V17 voltages ok?? We seem to be having a rash of output transformer failures lately......
>

Be sure ANTI-VOX isn't turned too high........ Cracked control element??

>

Usual spots, #12 bulb, pins, socket, plus shorted turn in INPUT RF Choke (nearby lightning)

Audio feedback, perhaps related to leaky C142
>

I take the front panel apart. It's not that hard, and you can get everything a lot cleaner that way!

When the noogie won't pull out, I use a soldering iron on the back and melt it until it yields.

Hi Garey,
It used to be, up until a day or 3 ago, that when someone posted to the list, and you picked "reply to all", you got his email addr as well as the lists, and the poster got 2 replies.
Not so now, you can't see the poster's addr., it only goes to the group.
If you view "message source", you can dig out his addr., but it's not very obvious, and the whole source file is pretty huge, lotsa html coding.
It's not that way on the Hallicrafters yahoo list (yet).

Joe -

It's a 'drop-in' replacement. I would recommend sticking with the 6HS6 in the 1st Mixer, but
it's fine for the PreMixer.

Personally, I'll stick with the HS6, yeah, $15 is more than the garden variety tubes, but you're
not likely to need another one, IF you need one now. There may be a reason Drake engineers chose it over the readily available 6AH6. Maybe not.....

No telling..... I just looked at the settings for DrakeRadio, and it was set to 'List Only'.
It used to show the sender's address in the header of the received message, but now you can't
just copy the sender ONLY.

I swear they're worse than engineers, they just can't stop fiddling with it!!! :-)

That said, I actually kinda like it. A lot of good stuff is lost by direct reply, so this just
makes it a little harder to cut the list out!

From: dj_coffman@...
Topic: 20828 Message: 20828

With a fresh set of 6JB6 tubes, properly neautrilized and tuned into a dummy load, where should one expect the plate control to be at full output? On 10M I consistently see the plate control with a dip just below the 10 setting. On a lower band, such as 40M, my plate setting is close to 7 3/4. Is this normal; it seems as if I'm running at the end of the plate capacitors value? 73, Doug - N9XTF

That's just about what I get. When the loading is at
minimum, that is the load control is max CCW the plate
tuning will dip almost at maximum CW. As the loading is
increased to bring the power up the plate tuning will become
lower. At maximum power output the tuning is near the limit
but within it. As the loading is changed at any frequency
the resonance is pulled slightly, this is a characteristic
of a parallel tuned circuit. Even though the pi network
doesn't look like a parallel tuned tank it is.

If the dip it right *at* the stop, it's usually a sign that either the finals are a different brand than the usual RCA or Sylvania or the neutralization is off. If it's *almost* at full CW, it's pretty normal.

Carry on...

Doug -

As has been said, 'near' the top is ok. The RULE for resonance is, as long as the Plate current
goes 'up' on BOTH sides of resonance, it's 'in range'! Same for tuning for a peak. As long as
the reading drops OFF on either side of a peak, it's ok. If only on one side, you've run into
the limit of the adjustment, which is probably NOT the point you want......

A list member sent this link to me for 'Triode Electronics' and thought others might be interested in it.

I am/was familiar with it, and there is a wealth of tube based information scattered around.
Granted, much of it is audio related, but since we owe our tube supply, (at least in part to
them,) it wouldn't hurt to be familiar with what they are doing!

<http://www.triodeelectronics.com/index.html>

An excellent site!

Fellow Drake Enthusiasts,

There will be a Drake Forum at Hamvention again this year. It will be 10:30 to 11:30 local time, Room 2, on Saturday. Please consider yourself invited. The first 125 attendees will receive a free, Drake logo pen. At the end of the Forum, there will be some free door prizes including Drake memorabilia, replacement parts, etc. Hope to see you there!

73,

Evan, K9SQG

Boy Garey, does that bring back fond memories!
Triode Electronics purchased the building and entire inventory of
the old Radio-TV Lab in Chicago and liquidated the "stuff" via the internet
a few years ago. See this site: http://www.yelp.com/biz/triode-electronics-chicago
http://www.yelp.com/biz/triode-electronics-chicago
I used to thread my way through literally piles and piles of transmitters, receivers, VFO's you name it! Can't remember for the life of me the former owner's name but he was quite a character! I bought lots of stuff from the store itself and also from the online auctions.
Yeah. Quite an experience for a young ham 50 years ago! I see Triode still operates out of the old Irving Park Road address of the Radio-TV Lab. I'll have to wander up there one day just for fun!

I was in Radio-RV Labs many times when I lived in Chicago in the early 80?s. I think the owner?s name was George, but I don?t recall his last name.

It was one of those great places that you just don?t find around much anymore.

I've located a scanned copy of the TR-7 service manual online. It's really helpful, except that the photographs are all black blurs.

Does anyone know a source for one that has readable photographs.

eBook preferred

TIA,

Geoff.

20842. tr-7 tuning dial

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-10 19:37:18 UTC
From: geoffrey mendelson
Topic: 20842 Message: 20842

In anticipation of opening up my TR-7 to fix the stuck tuning dial, I am hoping that the dial itself is stuck and not the PTO. I've repaired the stuck dials of an SPR-4, which was very similar to the 4 line dials. However I can't find anything on them, except a photo of a PTO assembly, complete with dial still attached sitting on a table.

From the looks of things, I think I will be able to remove the DR-7 and tilt forward the front panel exposing the dials. Do they get stuck like 4 line dials (with the application of oil)? Am I in for something far worse?

Do they really need to be calibrated? I understand that one can calibrate the quite accurately, but if you are only going to use a DR-7 do they need any real calibration at all (beyond reading the ends of the bands in the right places)?

Note that I have nothing better than the built in crystal calibrator and DR-7 to calibrate them to. I don't have a signal generator and I am out of range of WWV, CHU, and the EU time signal stations.

TIA.

Geoff.

20843. TR-7 AM filter workaround questions

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-10 19:51:50 UTC
From: geoffrey mendelson
Topic: 20843 Message: 20843

More TR-7 questions before I go to bed. :-)

I want to use the radio for AM reception. Once I get the tuning dial working, I am going to modify the filter board to add a "poor man's AM filter" and a 300Hz CW filter I have.

It seems that the standard is to put the CW filter in the A slot and the AM filter work around in the C slot. This is counter intuitive to me, AM filter in A slot, CW filter in C slot. Would this cause a problem for me? It probably will cause one for the next owner, but I am not concerned about that now.

The other question is that I have seen two different mods to replace the AM filter. The first is just a resistor, ranging in value from 150 ohms to 450 ohms. The second is a pad (http://www.alg.myzen.co.uk/radio/tr7/mods.htm#5). Any suggestions as to which is best?

TIA and 73.

steve and the gang

I've done it before, but it's been a while. I was wondering out loud if there was a simpler method than pulling all the knobs and de-mounting the dress panel. I'm getting lazy in my old age.

Still haven't got all the bugs out yet, but I had it sitting on 14.300 most of the evening and I heard stuff the net control didn't (most of that is propagation I'd bet!)

Called in with no traffic and got a good strong report.

It's misty out so I'll spend sometime with it this afternoon

Hi Geoff,
You can put the filters in any slot you want. Only the 2.3 kHz filter's position must not be changed as it is used for TX in SSB.
The resistor 'AM filter' works quite nicely. Never heard about the other method.

Me again...

You do not need more than the DR7 to calibrate it. In fact I hardly ever look on the dials. But it would be a pity if they were totally out of place. There is not much black magic in the PTO. You will see what it is all about when you dismantle it. You may take a few pictures in case you are unsure when putting it back together.
BTW if you need replacement for this brownish doughnot that usually gets stiff over the years. I have a piece of hose that fits just fine. Let me know if you need a piece.

Date: 2014-05-10 21:51:24 UTC
From: prosolar@...
Topic: 20848 Message: 20848

Gang,

making headway.

Found one leaky .01 cap in the audio circuit. Measured a few megohms dc.

Replaced it and it's brother.

Got plenty of audio now, running about '9 o'clock for room filling audio.

still having VOX issues. Either won't key or clicks on and off.

still got a whistle now and then. Pulling the 12AX7 makes the whistle go, so I'll poke around there.

Doing 120ish watts on all bands==== except for ten

Now, that band is another problem.

It's dead. I can't hear the calibrator nor my signal generator with 33mv being pushed in.

Yes, the crystal oscillator is running.

yes, I have transmit, but it's on 30.xxx

Hummm....

So question of the day

Drake wants you to measure the negative voltage on test point one, and adjust the crystal oscillator coils for max voltage.

now, when i do that, the oscillator stops. I find that about MINUS 3-4 volts seems to work fine. I can adjust the voltage to almost 7 volts but then the oscillator stops.

This radio is truly being a pain in the butt.

You can put any filter in any position your little heart desires, except the "default" 2.4 KHz which needs to stay where it is.

As for which resistor method is best, I don't know. I think most people just use the single resistor.

As long as you get the concentric dials lined up so the zeros are in the right spot when you are at 0 on the PTO it should be good to go. You will want to have about the same amount of calibration "slip" in either direction, but the TR-7 dial markings are never really very far off due to the synthesized HFO and excellent linearity of the PTO. Before I take one apart I place a black mark on the edge of the dial disks to mark the alignment point.

You will actually want to tilt the front panel a little bit first, this will give you room to pull the DR-7 straight up rather than fiddling around to get it past the top trim. Take the band swtich knob off and remove the two screws securing the band shaft detent plate on the back of the radio. Pull the band shaft far enough back to clear the front panel, then remove the top two (of three) screws on each side that secure the front assembly to the chassis sides. Loosen the bottom screws slightly and the front assy. will tilt nicely. From there you can remove the screws that secure the PTO to the front, disconnect three wires, and remove the PTO and drive mech completely from the rig.

The "crystal" calibrator in the TR-7 is quite accurate, as it is divided down from the 40 MHz master reference oscillator.

20852. TR-7 TX oscillation vexing me again

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-10 22:42:33 UTC
From: Jim Shorney
Topic: 20852 Message: 20852

My TR-7 is taunting me. This may be a clue for you injun-ear types that are smarter than I am.

I installed Bob Loving's stripped down version of the PIN diode attenuator a little while back, and that seemed to tame the 40 Meter oscillation issue nicely.

However, in preparation for running W1AW/0 on 17 Meters this weekend, I find that it hasn't left. It's just moved. When I run the rig into my Butternut vertical, with or without the tuner, I can see oscillations and/or spurs around and below 18.1 MHz on a spectrum analyzer and I can see their effect on the SWR meter. What's happening varies with mode and power level.

Driving a resistive load, such as my DL-1000 or (thankfully) the 50 Ohm resistive load in the input circuit of my NCL-2000, everything is clean and happy. So I'm not off the air on 17 Meters, I just need to run QRO. :)

Interestingly, I found that the 40 Meter oscillation seemed to be happening between 9 and 10 MHz. So what's 9 x 2? 18! Is it a coincidence that the problem has moved to17 Meters? Inquiring minds want to know...

20853. FS-4 Hooked up and Running FB

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-11 00:41:34 UTC
From: Whitebear1122
Topic: 20852 Message: 20853

I built up a simple cable today using RG-174 coax with an RCA plug on one end and (yikes) a paper clip and spade lug on the other :) I found the paper clip perfectly fit the HC-6 size socket. I tied the braid to a spade lug and connected that to the ground lug right below the crystal deck on the back. It was very obvious which side of the crystal socket the FS-4 wanted to be plugged in. I plugged it in the 'wrong' one first of course, and signals were attenuated. Plugged it into the other and signals were great.

I've taken the FS-4 and T-4XC/R-4C for a spin on the air on 20 meters and 17 meters, and listened to 40m, 30m, and 10m, and it works FB.

I did notice that when I set the crystal sector back to NORMAL with the FS-4 still plugged in that it seemed like the bandpass opened way up. I heard the same station but also heard stuff a little further down the band. I had already been forewarned about leaving the FS-4 plugged in while using the NORM position.

Its curious that the FS-4 styling doesn't resemble the T-4XC/R-4C styling. It's something beyond but not TR-7 styling either. This one I have is very clean and looks fabulous with the station. I notice the FS-4 knobs resemble the preselector and frequency selector knobs on the SPR-4.

To run the coax to the crystal deck I had to remove the crystal cover. The cover doesn't fit back on with the coax in place so I suppose it's something to get lost :)

I've got one more piece of Drake to hook up, the W4 wattmeter but I haven't been able to find it yet. It's squirreled away on the shelf. I'll be converting it to a PEP reading wattmeter before hooking it up.

73, Scott WA9WFA

20854. How Much Would A New T-4XC, R-4C station Cost Today? $1782

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-11 00:48:49 UTC
From: Whitebear1122
Topic: 20852 Message: 20854

A good friend knew I was getting the Drake gear so he left off a gift of a NOS Drake logbook and a Drake catalog from 1977 on his last visit. Wow in 1977 the catalog reports the T-4XC suggested amateur net price is $599, the R-4C $599, FS-4 $250, AC-4 $120, MS-4 $24.95, W4 $72, MN-2000 $220, MN-4 $110. Fun to look at the prices.

I used this website to calculate what those radios cost in today's dollars: http://www.usinflationcalculator.com

Based on the calculator, the $599 T-4XC, $599 R-4C would be equivalent to $2335 each, accounting for 289% cumulative inflation. The AC-4 and MS-4 would cost $584, for a total of $1782. I don't know what the actual selling price might have been.

It's interesting to put the cost in a perspective of today's dollars.

BTW the L-4B was $895 then, $3489 in todays dollars

Don't stop there.... Which cap was leaky??

The VOX is 'kicked' in with the first 'dit' or the first 'syllable' by C67/D67. IF the relay
clicks on the first key/sound and then drops right out, we're right back a week to NO SIDETONE
OSCILLATOR.

When you tune a crystal oscillator, you'll find that as you tune through resonance one side comes up smoothly, and the other side or resonance pops up very quickly. The STABLE point is
slightly down on the SLOW side.

Are the crystals the RIGHT crystals? In the RIGHT sockets?

Hey Evan and all, Thanks for your comments on your experience with the FS-4. I guess I was thinking that this 40 year old frequency synthesizer would be generating a lot more noise than newer devices. Like you, my new FS-4 works fabulous with no issues. I'm very pleased with it. I do notice that there is an effect on signals in the NORM position while the FS-4 is attached. Thank you. 73, Scott WA9WFA

In a fit of extravagance I bought two NOS main tuning knobs from KE9PQ. The fellow he's getting them from says they are NOS from the purchase of the Drake inventory several years ago. They do not come with the skirt. My new T-4XC and R-4C are in fabulous and I mean fabulous condition but the main tuning knob spinners were oxidized and a minor distraction. In a fit of craziness I splurged and bought two NOS knobs and put them on yesterday. They look fabulous, have a flawless NOS aluminum insert, and nicely black spinner.

Al -

I wouldn't say any are PRONE to failure, but I have seen 'some'. I assume we're talking about
"B" line here?

2N3904 or 2N4401 are reasonable replacements for the 2N3394.

2N3877A is a little higher voltage than you see typically, the 2N5550 is a reasonable replacement.

2N5950 is a good replacement FET for the PTO and Calibrator.

The 2N3904 is a pretty good generic replacement.

Watch out for different lead arrangements with some of the above.!

Scott -

Betcha' they're really TR-7 knobs!! :-) If you measure the 'depth' of the knob you'll find they are a little 'shorter'.! Unless he got them before 1998, cause that's what they were selling then.... No big deal, unless the circlip is too far back from the front panel, in which case the skirt can scrape the panel.

So if you don't mind 'non-standard' knobs ..... well then that's YOUR decision!! :-) :-)

I am thinking about purchasing an L-4B to round out my new T-4XC/R-4C station. I wonder if there are any L-4B's available in the Minneapolis/Saint Paul area first off, or if there are any for sale within driving distance, or if any for sale via shipping. I would be looking for 100% functionality and excellent condition, Eimac tubes preferable. Please email off list.

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-11 02:59:40 UTC
From: Jim Shorney
Topic: 20852 Message: 20867

Well, I was wrong. It's back on 40 Meters as well. Takes off into a nice 9-ish MHz sustained high power oscillation after I squirt some RF out.

Further observations:

30, 20, 15, 12, and 10 Meters are rock stable. 10 Meters seems to be the cleanest of all, a solid 100 Watts with no detectable funnies.

160 and 80 exhibit lower level spurs around 21 and 42 MHz related to RF output. Maybe related, maybe not. Don't know how far down they are, my "sampling probe" isn't flat across HF.

I would really like to blame the antenna, but that doesn't seen logical. On the stable bands it puts out clean power into not exactly flat SWR, up to 2:1. On 40 an 17 it takes off like a bat even with the tuner adjusted for 1:1 match. As I recall at one point on the bench I was able to get 40 to take off into a dummy load.

Something is changing. Every time I think I have this solved it seems to come back with a vengeance within a few weeks. What, other than electrolytic capacitors, could be getting progressively worse in this radio?

Scott,

That is interesting. Not sure I have an explanation for adverse effects. I do know, however, that the plug from the FS-4 has to be inserted with the proper polarity in the R4C.

Evan, I first noticed it when I switched back to the NORM position while the FS-4 was plugged in. I was hearing signals further outside the normal passband. I would switch the FS-4 back in and bandwidth would be normal. Yes I have the correct polarity because I first inserted it in a position where signals were greatly attenuated. I was advised of this possiiblity. I switched to the other crystal position and signals were now normal. I'm pleasantly surprised with the performance of the FS-4. Guess I was expecting it to be marginal or crappy. Not at all, it is very good and I'm cruising the WARC bands, and listening to 20m right now at 10:20 PM . 73, Scott WA9WFA

Evan/Scott -

It's pretty simple..... The 'intended' input for the FS-4 to the R-4B/C is to the 'common' lead to ALL the crystal sockets. This is the Emitter of the BAND oscillator, which becomes a
'Grounded Grid' (ok, 'Grounded Base') amplifier with its output to the PreMixer Grid. This means a single pin, (coax center conductor) goes into ANY of the crystal sockets to the LOWER
pin. Shield of the coax goes to the chassis, NOT to the 'other' crystal pin. With this setup,
switch off of NORM, and you've got a nice little amplified BAND signal for the PreMixer. The
FS-4, turned off, is just a capacitive load across the INPUT of the BAND oscillator, reducing
the gain and quite possibly 'encouraging' strange behavior from those 3rd overtone crystals,
which doesn't take much!

Some think they can make up a neat little connector from a dead crystal, and plug it into a specific XTAL socket, and then 'choose' that position when they want to use the FS-4. This scenario connects the output of the FS-4 to the OUTPUT of the BAND oscillator and drives the
PreMixer Grid via the BAND output transformer, backwards! Switch to NORM, and you're back on
crystal control! NOT! This way, when you switch away from the 'specific' socket back to NORM,
you still have the shield of the coax (ground!) connected to the INPUT of the BAND oscillator.... Drags it down, AND may make the crystal you then select somewhat 'squirrelly'.
Again, these are 3rd overtone crystals for the most part, and don't take kindly to stray loads.

I'm very pleased with it. I do notice that there is an effect on signals in the NORM position while the FS-4 is attached. Thank you. 73, Scott WA9WFA

One of these on eBay. Anyone know what it is and what it does? The seller was pretty much in the dark about it and I've never heard of it. Can anyone shed some light on this thing?

Topic: 206 Message: 20874

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

73, Garey - K4OAH

Jim -

You DO find interesting problems! :-)

I don't think it's related to just 'YOUR' radio. I've seen several that want to take off on 40M. I suspect that's the maximum gain point of the PA design, so takes off first??

RF getting back into the '723 in the PS-7? Do you have anything plugged into the ACCY jack? It's connected directly to the current sense input of the '723.

Try running the PA ONLY from a supply other than the PS-7. And vice versa....

I know there are Drake nets out there but I am usually at work when there on. The yahoo drake group should set up some times and a frequency or 2 for a little rag chew type net. I know there is alot of people that would like to talk to each other over something other than email. Has anyone in the group here tried this already?

Garey and the gang

the leaky capacitor, a .01, was across the audio transformer. I don't remember what name it is called.

Found a 3.3M resistor in the VOX circuit that was well over 5 Megs. Replaced the .1 cap.

Still a bit flaky...

Found the reason why I get a squeal now and then, but not the fix. I found that turning up the mic gain to max was the culprit. IT's not suppose do that, so, I'll need to dig deeper into the speech amplifier.

I can hear the calibrator signal now on ten, but it sounds super rough as though the agc has ac riding on it. Calibrator sounds completely normal on other bands.

I think I found the problem for low output on 80. It's alignment. On the high end, 4.00, bang! 150 watts on the low end, 3.5, 50ish watts.

The plot continues....

Ah, the old 'C136' trick! :-)

If the resistor is sitting up on 'posts', it's the VOX DELAY resistor, select at test, R106.
Increase would SLOW the VOX drop-out time.

C143 is the VOX integrating capacitor, leakage would SPEED UP the drop-out! May have canceled
each other out!

Simple feedback, Probably C145B.

Maybe 0A2. You're listening to the ~290th harmonic, so any ripple or noise on the CAL signal
is multiplied too!

Possibly poor solder/connection to one of the LOAD capacitor sections.

You're getting there!!

Hello.

I have a TR-7 with a problema, the transceiver is standing for several years.

And now I'm back to using it but I have a problem, the VFO is always kept at the same frequency (10.600.0 approx) if you change the throw.

Someone can help me fix it.

A greeting.

Usually stable into a dummy load, I could only get it to oscillate on 40 Meters into a dummy load if I turned the predriver gain up higher than necessary.

20882. Re: [DrakeRadio] TR-7 TX oscillation vexing me again

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-11 16:46:28 UTC
From: Jim Shorney
Topic: 20852 Message: 20882

Good suggestions, old man. I know that there are other rigs that do it on 40, so I would really like to crack this nut. Yes, from my earlier testing there seems to be a gain peak in the 9 to 10 MHz area of the system. The output filtering may figure in there somehow, because 30 Meters is rock stable and it is in the same band segment as 20 Meters. They only seem to oscillate in the 40 Meter band segment ... and now 17 Meters. Interestingly, 15, 12, and 10 Meters are stable. 17 Meters is in the 15 Meter band segment. Figure that one out.

I don't think it's supply related, either. I do have my SP-75 plugged in to the accessory jack. Although I can get the PS-7 to shut down on 80 Meters if I turn the CW level "up to 11", that's a different issue. My bench test supply is an Astron 35M, and the radio will take off just as happily on that one. The idea of trying the PA deck on a seperate supply is interesting. I also thought of swapping PA decks with the spare TR-7 to see what happens.

This is where I really need an engineer that understands this stuff. I know you're a tube guy, but I do appreciate the suggestions. I'll be able to tinker with it more after the W1AW/0 craziness is done with. I need to tear down and re-lube the PTO in the spare rig before I can swap it into the system anyway.

I think my next project will be to re-cap all of the electrolytics in this radio. It's probably not at all related to this problem, but I do see a couple of other areas that could benefit from it.

Subject: Re: [DrakeRadio] FS-4 Question

Evan/Scott -

It's pretty simple..... The 'intended' input for the FS-4 to the R-4B/C is to the 'common' lead to ALL the crystal sockets. This is the Emitter of the BAND oscillator, which becomes a
'Grounded Grid' (ok, 'Grounded Base') amplifier with its output to the PreMixer Grid. This means a single pin, (coax center conductor) goes into ANY of the crystal sockets to the LOWER
pin. Shield of the coax goes to the chassis, NOT to the 'other' crystal pin. With this setup,
switch off of NORM, and you've got a nice little amplified BAND signal for the PreMixer. The
FS-4, turned off, is just a capacitive load across the INPUT of the BAND oscillator, reducing
the gain and quite possibly 'encouraging' strange behavior from those 3rd overtone crystals,
which doesn't take much!

Some think they can make up a neat little connector from a dead crystal, and plug it into a specific XTAL socket, and then 'choose' that position when they want to use the FS-4. This scenario connects the output of the FS-4 to the OUTPUT of the BAND oscillator and drives the
PreMixer Grid via the BAND output transformer, backwards! Switch to NORM, and you're back on
crystal control! NOT! This way, when you switch away from the 'specific' socket back to NORM,
you still have the shield of the coax (ground!) connected to the INPUT of the BAND oscillator.... Drags it down, AND may make the crystal you then select somewhat 'squirrelly'.
Again, these are 3rd overtone crystals for the most part, and don't take kindly to stray loads.

Subject: [DrakeRadio] Yahoo drake radios group net?

I know there are Drake nets out there but I am usually at work when there on. The yahoo drake group should set up some times and a frequency or 2 for a little rag chew type net. I know there is alot of people that would like to talk to each other over something other than email. Has anyone in the group here tried this already?

Jim -

OK. Well I spent quite a few years as an RFI/EMI engineer for NASA, and I'll tell you there are
LOTS of ways for RF to get where it's not supposed to!! :-)

Don't forget there is 'conducted' interference on power and control leads as well as 'radiated'.

Yep, I get that. But connected to a PS and a dummy load on the bench is about as different from being integrated into the radio system as you can get, and I was able to make it oscillate there too. That would seem to pretty much narrow it down to what's inside the box.

Jim -

Yes, that's a good setup. Just don't forget pulses of current (DC and RF) to the PA go through
the same cable as the the current to the 'rest of the radio'. There are 'common mode' interactions.

By the way, my work experience (design) was 100% solid state.... Mostly transmitters, just VHF
and UHF. Nothing much over 40W........

Radio astronomy don't count, the _IF_ was at C-Band (4.5 GHz). Up converter from L-Band (1.2
GHz), and down converters from Ku (15.5 GHz) and K (22 GHz). Of course, all cryogenically cooled down to ~10 degrees Kelvin, so not real pertinent here!! :-)

20892. Re: [DrakeRadio] FS-4 Question

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-11 19:00:54 UTC
From: Paddy Ryan
Topic: 206 Message: 20892

Gary

Thank you for clarifying this. The FS4 manual clearly states connecting the screen to the chassis and the centre to the xtal socket. I must admit that I connected to the two xtal sockets with a home made ‘plug’ as you described but now I know better and will modify my plug to go to ground and the lower pin of the xtal socket on my R4C.

Subject: Re: [DrakeRadio] FS-4 Question

Evan/Scott -

It's pretty simple..... The 'intended' input for the FS-4 to the R-4B/C is to the 'common' lead to ALL the crystal sockets. This is the Emitter of the BAND oscillator, which becomes a
'Grounded Grid' (ok, 'Grounded Base') amplifier with its output to the PreMixer Grid. This means a single pin, (coax center conductor) goes into ANY of the crystal sockets to the LOWER
pin. Shield of the coax goes to the chassis, NOT to the 'other' crystal pin. With this setup,
switch off of NORM, and you've got a nice little amplified BAND signal for the PreMixer. The
FS-4, turned off, is just a capacitive load across the INPUT of the BAND oscillator, reducing
the gain and quite possibly 'encouraging' strange behavior from those 3rd overtone crystals,
which doesn't take much!

Some think they can make up a neat little connector from a dead crystal, and plug it into a specific XTAL socket, and then 'choose' that position when they want to use the FS-4. This scenario connects the output of the FS-4 to the OUTPUT of the BAND oscillator and drives the
PreMixer Grid via the BAND output transformer, backwards! Switch to NORM, and you're back on
crystal control! NOT! This way, when you switch away from the 'specific' socket back to NORM,
you still have the shield of the coax (ground!) connected to the INPUT of the BAND oscillator.... Drags it down, AND may make the crystal you then select somewhat 'squirrelly'.
Again, these are 3rd overtone crystals for the most part, and don't take kindly to stray loads.

> Evan, I first noticed it when I switched back to the NORM position while the FS-4 was plugged in. I was hearing signals further outside the normal passband. I would switch the FS-4 back in and bandwidth would be normal. Yes I have the correct polarity because I first inserted it in a position where signals were greatly attenuated. I was advised of this possiiblity. I switched to the other crystal position and signals were now normal. I'm pleasantly surprised with the performance of the FS-4. Guess I was expecting it to be marginal or crappy. Not at all, it is very good and I'm cruising the WARC bands, and listening to 20m right now at 10:20 PM . 73, Scott WA9WFA

I am one who hates nets for a particular radio. Not much gets accomplished, no time for anything, can't hear everybody, some monopolize the net, those who are interesting don't speak. Just a bunch of wasted time in my estimation. I am sure others will disagree and some will agree. It's just you will never hear me on one of them. They are impractical and time wasters. No depth to any of them.

And I confess that I have learned useful tricks with my radio, and enjoy the expertise of others. I'll check in if at all possible, though until I get some hi-fi interference resolved, I won't be running my hi-tech (TS-590) and vintage (Johnson Viking KW) combo. Humbly suggest NCS be taken by whoever can hear the most stations.

Garey, Sherwood may still be selling it. I had seen this recently on Sherwoods webpage and just checked it today to copy it and post here. I wonder if anyone here has recently bought this set up. I don't plan to reach around back and disconnect it when I use the internal crystals. 73, Scott WA9WFA

FS-4 Interface Kit

The Drake FS-4 band synthesizer provides the R-4C (and some other Drake models) with general coverage. The stock connection to the radio was a kluge, requiring the user plug a short cable into an accessory band crystal socket. Drake recommended unplugging the connection when the normal band crystals were used, as the feed loaded down the injection oscillator. For over 20 years we have offered the FS-4 Interface Kit that solves this connection problem. The kit consists of a TO-5 RF relay, and several RCA jacks. When installed, turning on the power to the FS-4 keys the relay, switching out the band crystal bank, and injecting the FS-4 signal.

FS-4 Kit: $69.00 US
It is field installable. Installation takes about 2 hours.
If we install the kit while servicing your R-4C, the labor charge is $49.00 US

My generic cable is "special". I built it with that biga$$ wire that GE provided for trunk mounting the 110 Watt Rangr mobile rigs. My run is quite a bit less than trunk-to-engine compartment, and voltage drop is nil. I've also isolated the high current B+ feed, with more mundane wire for the low current rail. It doesn't get much better than this for a home-made TR-7 cable. The negative wire is still common to both, but it still works pretty well. To fully isolate the high current would require surgery inside the radio, and I haven't got that ambitious. Any idea what the current rating per pin is on the power connector?

The PS-7 cable is pretty robust as it is, but I also isolated the high current rail there.

do you think Saturday at night would be good Ray? if we did it mid evening we could get on 40 somewhere. Ill listen around and find a good spot with alot of room around it above 7175 so generals can get involved to. If you have any suggestions that would be great. It seems like every time you tune around you hear a collins net going on but not near enough Drake nets. Everybody loves em so I think it would be fun. And really great if we could get some of the guys like Garey, Steve and Jim to do some tech tips. I think it would be better to have it just like a rag chew not a normal check-in net. What do you think?

Pat -

I should clarify this a bit further... I "think" the C-Line is not consistent on which pin is
'common' on the crystal sockets. I don't have one open right now, but I seem to recall that the
C-Line uses a PC board for those sockets, rather than individually wired as in the earlier receivers.

The pin you want to connect the 'HOT' lead from the FS-4 to is the one that is common to ALL the
crystals. It looks like it could be either the 'top' - OR - the 'bottom' pin depending upon which row it's in. Of course it made no difference for crystals, so didn't matter then.

If you can't see which pin is which, an ohmmeter check should show 0 ohms between two adjacent
pins. Either of those will work as will any others in that 'row'. The pin you want is the one
that is common to the one next to it!!!! I'm confusing myself... :-)

Thanks Garey for the detailed description of the circuit. Yes I can understand how the unpowered FS-4 output buffer or amplifier circuit hanging on the R-4C oscillator would affect it. I just took a peek at Mouser.com and they have a ton of RF relays in tiny packages that are cheap, under $6. Just need a coil that is compatible with what ever dc voltages are available in the FS-4. The coil currents are pretty low, 50 ma range. Wiring would be easy, just remove the FS-4 output from the RCA jack, run it through the relay, and connect the relay output to the RCA jack. Relay would activate whenever power is turned on.

On my R-4C it's the lower pin. I first tried the upper pin and it didn't work right, moved it to the lower pin and it's working well. I ran the coax shield straight down to the chassis ground stud below the crystal area. 73, Scott WA9WFA

Jim -

The 2400 Series Cinch-Jones connectors are rated at 15A per contact. That is for the 'real' C-J _phenolic_ body. I don't know what the MOLEX type are rated, but I believe they just have
a plastic body.

The 300 Series are 10A per contact.

Keep us posted..... I would be surprised if the culprit turns out to be an electrolytic. My next guess would be lead routing/card grounding. Those little copper springy things aren't real
consistent. You'll also notice if you open a newer TR-7 that there are a LOT more of them than
there were in the early ones!! :-)

Can you get it to oscillate 'under control'? Where it'll oscillate without destroying itself?
Will it oscillated without the PA?? That would allow you to probe for hot spots. If you can at
least control it you could go through with a few ground clips. Just a thought, have you done
the 'screwdriver tour' in a while???

It would be nice to see something get started here on the left coast.

We have a nice group of operators that have a Collins Net on Friday evenings. True, not much discussion about the radios, but a nice time is had just the same. Gives everyone an excuse to fire up the rig.

Just an idea....

The catch is you need to disconnect it at the R-4C end of the cable.! The point is to get that
cable capacitance off, so it doesn't look like a bypass capacitor. RG-174 is ~ 25 pF/ft, so that's like connecting a 50-60 pF cap right across the input to the amp. This is what upsets
the applecart!

Just thought I would let everyone in the Drake world know I changed 5 pan head screws on one of my Drake rigs today as the old ones had a bit of tarnish on them. I'll let everyone know when I get more replaced over time. The we will go on to feet and bumpers!

Yea, but did they get answers? Could have gone down to Radio Shack and done that without firing up the Drake.
Lee, w0vt

We had 19 check-ins today under terrible band conditions. I think
there were 5 people with technical questions. Everyone seemed to have
a good time.

Jim

FWIW, I have S/N's 1XXX, 6XXX and 9XXX TR-7's. I have had to work on all 3 units for various problems and what Gary is noting does make sense as over the production cycle extra grounding was added to the boards in the cage. My 1XXX unit had an earlier generation 2nd mixer board and this board does like to take off if the grounding tabs are not secure. Ended up not so sensitive on the later version of the 2nd mixer board.

I have 1XXX and 9XXX open on the bench just now so if you need a reading to compare to your unit, I may be able to assist.

Do you have the first or second generation power amplifier ?

Jim -

The 2400 Series Cinch-Jones connectors are rated at 15A per contact. That is for the 'real'

C-J _phenolic_ body. I don't know what the MOLEX type are rated, but I believe they just have

a plastic body.

The 300 Series are 10A per contact.

Keep us posted..... I would be surprised if the culprit turns out to be an electrolytic. My

next guess would be lead routing/card grounding. Those little copper springy things aren't real

consistent. You'll also notice if you open a newer TR-7 that there are a LOT more of them than

there were in the early ones!! :-)

Can you get it to oscillate 'under control'? Where it'll oscillate without destroying itself?

Will it oscillated without the PA?? That would allow you to probe for hot spots. If you can at

least control it you could go through with a few ground clips. Just a thought, have you done

the 'screwdriver tour' in a while???

20918. T-4XB 40 AND 20 METER XTALS??

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-12 04:20:02 UTC
From: David Nichols
Topic: 20918 Message: 20918

My 40 and 20 meter frequencies are way off. I thought I would ask if I had missed some adjustment before I order more crystals. As Im sure some of you know, they dont come cheap. I got the new one installed in the TR-4cw for 40 meters and it is right on now.
So, back to the T-4XB. 75, 15, and 10 meters are good.

On 40 meters, when the dial is set to 7.0, I get 5.7 MHz out. I didnt notice anything odd when I was doing the alignment.
On 20 meters, when the dail is set to 14.0, I get 11.3 MHz out. The back trimmers for this band are as tight as I can get them. Thats when I looked a little deeper.
What has me really wondering is that I swapped the 20 meter xtal with my R-4B and got the same results. I just dont see both crystals being equally off when they came from totally different environments. But who knows? I have not put the signal gen to the receiver yet to see if its off.

The TR-7 I am trying to fix had its serial number covered over with some sort of black paint. An Israeli ID number of the old format (not used in at least 20 years) was carved into it. I expect that since that police in the US told people to scratch out serial numbers and carve in their Social Security numbers to deter theft, it was done by someone who came from the US in the 1970's or 1980's with their TR-7.

Is there any other way to determine useful information, such as what generation which boards are, and so on?

Is there a hidden second copy of the serial number, like the VIN on cars?

Did anyone know a US ham who moved to Israel around then who was a big RTTY user and modified his TR7 for it?

TIA

Geoff.

David -

Those crystals are not off, they are OFF!! As in they're NOT running at all. :-) You'll notice that if you turn the dial, those two frequencies you note DON'T move..... Hmmmmm.

Now, if you've 'tightened up the loose screws' on those trimmers, you may have detuned the PreMixer so far that IT'S not running.

Anyway, those two frequencies you mention??? The first one is actually 5.645 MHz, and is the
CAR OSC running through because there is no PreMixer signal at V2. The second one, the second
harmonic of the CAR OSC, same reason. You'll notice that the PreSelector dial is nowhere near
the band segments.....

So. First step is to back off on those trimmers. None of the trimmers in this radio need to be
'tight'. A few may end up pretty 'loose', but none tight. Put your counter near the BAND
oscillator, the transistor is on the board right near the crystal sockets under the chassis.
Set the MODE switch to TUNE, with GAIN at 0 (MAX CCW). Look for signals at 18.1 MHz (40M) and
25.1 MHz (20M). Try for the one at 32.1 MHz (15M) first, since we know it's working. If one or
both are actually there, put your counter (or preferably a scope if you have one) over on T5.
Set the PreSelector control to within the marked segment for each of the two bands as
appropriate. With the PTO dial set to 0.000, you should find 12.645 MHz on 40M, and 26.645 MHz
on 15M. Unless you have adjusted T4 and/or T5, you don't need to touch them, yet. Adjust the
two _INJ TRIM_ trimmers (frontmost) for maximum signal on each of the bands at those two frequencies.

Now, those two rearmost trimmers _RF TRIM_ on each band need to be adjusted back from where you tuned them when you were trying to tune them to the wrong frequencies, (well outside their
design goal!) Again, with the PreSelector set appropriately, and MODE switch to TUNE, GAIN to
about 10 o'clock, and adjust them for maximum output. Set the LOAD control to 0, (CCW,) and
WATCH for drive to the PA, the PLATE meter will JUMP up suddenly when you get the trimmers in
the correct range, so be prepared to DIP the PA immediately and reduce the GAIN for no more than
150 mA at the DIP.

These adjustments will all be refined as part of the alignment procedure, once everything is
working! Watch the PLATE current, DIP the final......

Ken -

Very nice!! Was the chassis that good, or did you do some 'copper restoration'?

The "B" knob isn't 'original' but a LOT of us purchased the B-Line knob and skirt because it was
such an improvement over the flat skirt of the original. Unfortunately the 'other' significant
improvement in the B-Line, the 'above the belt' black labels, was more expensive, AND, back then
Drake would only sell you a new front panel AFTER you sent them your 'old' one, so you couldn't
'update' a radio. Plus, it cost $10!!!

No copper restoration needed. There are just 2 small blemishes on it and they are in locations that you really have to look for them.

Yes, the B-Line knob is a nice feature, and that's the way it came on eBay.

Some good news..

Several resistors in the mic amp section were way off values. A 47K read
64K and a 330k measured 490K.

Sub in a 10 mf for C145B with no improvement.

However, a 68 pf from pin two to ground, seemed iffy. Replaced with new and
now the mic gain can be turned fully clockwise with no howl.

Still nothing on 10 meters

but since I'm feeling cocky now, I'll tackle a half dozen of those pan
screws before moving on

20926. Re: [DrakeRadio] T-4XB 40 AND 20 METER XTALS??

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-12 20:23:19 UTC
From: David Nichols
Topic: 20918 Message: 20926

Ok Garey, I just know that Im going to drop the "e" in your name sooner or later. I have a brother named Gary. He lives over in Princeton, WV.

Thanks for giving me a direction to head in. I had to go to town this morning and will again later this afternoon. My wifes car is one on the airbag recall and is being repaired today.

Anyway, my first thought was to to really give the band switch another looking over and cleaning since some of the segments didnt really clean up as well as I had wanted. Well a couple still have not cleaned as well as I would like but are better. The two segments attached to the divider the third and fourth from the front are a bit warped but seem to be making up as they should.
On another note, someone else has been all over this deck. It looks like they took the shotgun approach and hit just about everything with the solder pencil. The trimmers where tight when I got it so not really my fault. Ill own my mess ups but I dont take credit for someone elses work. hi hi
I may have found some life on 40m now but as you say the Pre selector is out there. I found about 18 watts with the rf tune at the top end of 80m and my signal is at 7.0 MHz and the frequency counter hooked up to Q3 on board 1 is showing close enough to 18.1 (18.09980)

When I switch to 20m I get 25.09959, counter readout doesnt change when I switch to tune. So this is probably close enough to the readings you said I should see. But I dont have life on 20m yet.
I have not touched T4 or T5, ok its looking good on the transistor Ill have to figure out how to pickup something at T5.

25.1 MHz (20M). Try for the one at 32.1 MHz (15M) first, since we know it's working. If one or
both are actually there, put your counter (or preferably a scope if you have one) over on T5.
Set the PreSelector control to within the marked segment for each of the two bands as appropriate. With the PTO dial set to 0.000, you should find 12.645 MHz on 40M, and 26.645 MHz
on 15M. Unless you have adjusted T4 and/or T5, you don't need to touch them, yet. Adjust the
two _INJ TRIM_ trimmers (frontmost) for maximum signal on each of the bands at those two frequencies.

Now, those two rearmost trimmers _RF TRIM_ on each band need to be adjusted back from where you tuned them when you were trying to tune them to the wrong frequencies, (well outside their
design goal!) Again, with the PreSelector set appropriately, and MODE switch to TUNE, GAIN to
about 10 o'clock, and adjust them for maximum output. Set the LOAD control to 0, (CCW,) and WATCH for drive to the PA, the PLATE meter will JUMP up suddenly when you get the trimmers in
the correct range, so be prepared to DIP the PA immediately and reduce the GAIN for no more than
150 mA at the DIP.

These adjustments will all be refined as part of the alignment procedure, once everything is
working! Watch the PLATE current, DIP the final......

Charles,
Would be nice to have a left coast group there doesn't seem to much going on here on the left coast in the way of Drakes can't even find anyone to do repairs. I have a friend who's real handy at fixing tube rigs I've tried to get him to start a service, but he wants no part of it, I guess he doesn't want to deal with the (ham) public don't blame him at all.

20928. Bias current drift

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-12 23:06:11 UTC
From: Brian and Beth Miller
Topic: 20928 Message: 20928

As I mentioned in a recent posting, I am monitoring the voltage across R36 to set plate bias. I turn the T4X-B on and let it warm up for a few minutes, then, with GAIN fully CCW (but still on), I measure the voltage across R36. But I observe that the voltage drifts. There are 2 factors involved.

- How long the T4X-B has been on GAIN full CCW, mode SSB, prior to setting mode to TUNE and setting bias.

- How long the T4X-B has been on GAIN full CCW, mode TUNE, prior to setting bias.

Without altering the bias pot on the power supply:

If I only let the xmitter warm up for 5 minutes I measure 59.4mA plate current.

If I let the xmitter warm up for 35 minutes I measure 65mA plate current.

In the 2 cases above, plate current was measured immediately after setting mode to TUNE.

If I let the xmitter warm up for 35 minutes, then set mode to TUNE and leave it there, the plate currents slowly rises. It stabilizes after about 20 minutes at a value of 76mA.

I checked Vbias out of the AC-4; it does not drift.

From minimum (59.4mA) to maximum (76mA) I measure a change of 27%.

How do I measure the plate current? I assume I want to let the T4X-B warm up fully; maybe 30 minutes to be conservative, but how long should I leave it in TUNE mode before I attempt to set the bias?

Brian -

That sort of 'idle current creep' is usually the result of 'gassy' finals. More accurately 'grid emission'. Often the result of a mishap of some sort, off resonance, antenna problem, trying to tune up on the 'wrong' antenna, or other abuse of the PA tubes.

If the output on 10M is still close to 100W, then I'd just wait until it stopped drifting and
then set it for 70 mA. Then let it warm up for about 30 minutes or so before transmitting. On
CW it won't really matter, the IMD might be a little higher on SSB until the PA reaches it's
'operating' temperature.

Easiest way to monitor is to measure the voltage across R36. Measure R36 first and record the
ACTUAL resistance. Then measure the voltage drop across it and calculate the current. You can
measure the voltage from the top of the chassis. There is a wire from the 'inboard' terminal of
the meter that goes over to the METER switch (between TUNE and LOAD controls) to a resistor.
That is R38, the 'select at test' calibration resistor. Put your DVM from the 'outboard' meter
terminal to the 'other' lead of R38 at the switch. This will give you the voltage across R36
and you can calculate the current using the recorded value you have for R36.

From: rochep@...
Topic: 20930 Message: 20930

Instead of giving the on/off switch on my R4A and T4XB a workout, I have the rigs ON, plugged into a surge arrestor/outlet strip and control the ON and OFF of the rigs by simply turning ON/OFF the surge arrestor/outlet strip. Is there anything wrong with doing this?

The surge arrestor is probably useless. The MOV based ones are poor at best and dangerous at worst. The Trip-Lite ones are good, and since they are now off patent, someone is cloning them and selling them at 4 times the price to the high end audio and TV market. :-)

Paul -

I assume you're doing this primarily to protect the power switch in the radio. Yes, it is an
excellent idea, I do the same. Unless the power switch on the radio is a standard toggle switch, it will be very difficult, at BEST, to find a replacement. Any sort of rotary control
with the switch 'on the back' is very rare these days. The only one seems to be the 500k, audio
taper, 'volume control' used on literally millions of table radios since the 40's, and it's not
just everywhere. Best chance these days is the guitar people. A 'dual' control, such as on the
TR-4/C, TR-7, etc., with two different value pots with a high current switch on the back....?
Unh-uh.

If I want to control specific pieces, I turn them on or off BEFORE turning the strip ON. Again,
the guitar/music people have multiple outlet strips with an individual switch for each outlet.
Very nice. They seem to have had the same problems we have, (old equipment/combination controls,) and fortunately there are enough of them to drive a market!

rochep was asking about using the switch on the outlet strip as a master
switch for his gear, avoiding use of the Drake power switches which are
a known failure point. Not my way of doing it but perfectly OK.

Tripp-lite is much better than MOV but how is an MOV surge protector
dangerous? I know the overall quality of the whole thing id often poor.

Another option is to use one or two CL-90 thermistors as a current in-rush limiter. These work reasonably well for receivers; I wouldn't use them for most transmitters/transceivers. The thermistor will limit initial current, help to save the on/off switch, and also bring down high mains voltage back into the 115V-117V AC range where power companies are pushing upwards of 125VAC as a normal line voltage. The thermistors get hot and if they're installed under a chassis, it's best to place them near a vent hole.

Yet another option is to use a solid-state relay (SSR) installed in the equipment. These work well for both Rx and Tx. I designed a PCB for my boatanchor gear that uses a choice of zero-crossing or random crossing Omron SSRs. With the SSR, the on/off switch only passes a few mA of current and never sees an in-rush.

Paul,

Does the PCB you designed small enough to mount internally? Also, I?m curious as to what advantage a random crossing SSR would have. Can you give us some more details on what you developed?

I've installed thermistors in my L4B and L7 amps and have used them successfully for several years. Too, one needs to investigate some of the "inrush current protectors" on the market since some of them, well, don't do that. I bought two of these devices knowing what they really are, just to have a "remote" on/off switch for my linears. As to limiting inrush current, these devices afford maybe 25-50 msec of current limiting at best, well under the time it takes for filaments to heat and capacitors to charge. Thus the use of thermistors.

73,

Evan

You can see the board size on my QRZ.com page where its installed in a Hallicrafters receiver -- I think its my SX-100.

Zero-crossing helps to limit current since the switch internal to the SSR does not activate until the AC sine wave crosses 0 volts. However, you'll find warnings from SSR manufacturers about not using zero-crossing types on heavily inductive loads and even some transformers. In those cases, random turn-on (RTO) types are preferred.

rochep was asking about using the switch on the outlet strip as a master switch for his gear, avoiding use of the Drake power switches which are a known failure point. Not my way of doing it but perfectly OK.

Tripp-lite is much better than MOV but how is an MOV surge protector dangerous? I know the overall quality of the whole thing id often poor.

The "surge prevention" burns out a little at a time, and eventually you end up thinking you have something you don't.

If they don't have a fuse in series with the power line, they are really dangerous.

If there is enough of an overload, and no fuse, they short out the full power line current and this often happens with a band and smoke. If they are in a plastic enclosure it may catch fire.

Geoff.

Thanks, I'll do that! Every little bit helps.

I probably should see if I can find an "A" tuning dial and skirt, to make it more correct but the "B" one is really nice.

However, this wasn't restored as a collector's version, just as a good working radio.

I am more worried about seeing a potentiometer wear down to nothing. We had that problem with our Moto HT's on the railroad in daily use.After countless on/off cycles the mil spec radios developed worn out volume pots.. My proceedure is to leave things powered up and switch an outlet on/off. 73 de n8aft

I've been using the old Computer monitor switch stands. Amazon has one similar to what I've been using, only I've been picking mine up at hamfest for about $5 or less.

http://www.amazon.com/Tripp-Lite-TMC-6-Protect-Protector/dp/B0000AKA90/ref=sr_1_2?s=electronics&ie=UTF8&qid=1400006054&sr=1-2&keywords=computer+monitor+AC+outlet+switch+box

They are big enough you can set a radio on top of them. Put two or three side by side and you can switch on most anything in the shack within cord length.

I'm not interested in surge protection, only the on/off switch feature. Just leave all of the radio switches on and do the on/off through these.

Another question (probably for Garey)...
I see in your photos, it looks like the bottom cover is the same as the one on my T-4X, not my R-4A. There is a cutout on the front right that allows the external xtal socket.
Did Drake simplify their inventory at some point and use the same cover?

Hi Ken,
I have had 2 R-4A's over the years. I love them, they are the best receiver ever!
To me the B knob looks wrong but I guess the skirt would be more "visible".
My first R-4A was an early one, had the 5KHz markings and no preselector vernier.
My new one (since 1980, hardly new!) has 25KHz markings and the vernier. Yours
must be between my 2, you have 5KHz and vernier!
I was sooo thrilled when I sharpied my radios. My T-4X was almost grey but in
20seconds it looked like I remembered it back when I had the first R-4A in 1967.

Gary -

Good question... Crystal control was not standard until the T-4XC. However the side crystal mount WAS of course in the T-4. Even the T-4B didn't use that, it had a 10 socket crystal bank
inside a door on the right side of the upper cabinet, and just a crystal switch on the front
panel. Even the T-4B used the same bottom cover, with a black disc mounted with a single screw
on the chassis cutout. Apparently they decided to put the holes and the cover cutout on all models, covering it with either black tape or for a while with a black disc with a screw through
the center of it.

I can't find any record of a 'kit' from Drake to add a socket, it was just a socket with a ceramic trimmer across it and coax over to the PreMixer, so wouldn't have been difficult to add.
Of course there was no front panel provision for selecting either PTO or crystal, so not a 'convenient' feature!

I doubt that cover was ever used on the receivers, at least not by the factory. If ham were to
swap the bottom covers, he'd just have no cutout over his black tape! :-)

20953. T4XB relay gets stuck

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-14 01:38:16 UTC
From: rochep@...
Topic: 20953 Message: 20953

I have read that a T/R relay that starts out fine, and then gets worse as your TX warms up(sticks for longer and longer time and eventually NEVER releases to RX) , is a sign of a gassy 6EV7 VOX tube. I have that problem. When I first turn on my TX I can tune up, all is fine, and maybe a quick DX "5NN" contact. But after 3 minutes or so, when I key the rig it stays in transmit. Have to actually turn OFF the power to get it to trip! Happens in dummy load; I can simply close my PTT switch, NOT actually send code, and when I release PTT it does not open the relay.

I have now bought TWO "new" 6EV7 tubes, no cure. The T/R relay setting seems VERY sensitive to the vox gain/anti-vox/vox delay settings. I like a VERY quiet sidetone: I tried increasing it and does not help. Am I perhaps setting up the rig wrong, or should this type of behavior really a sign of yet another bad 6EV7?

(checked resistances, only wierd ones are :
V8 6HS6 pin 6 is 19K instead of 90K and pin 7 is 51K instead of 470 ohms
V10 6EV7 pin 2 is 850K instead of 500K.

This is with a DMM, NOT a 11 meg VTVM

(all voltages check out OK, even those on 6HS6).

(my T4XC uses a 6EJ7 instead of a 6EV7, is this an exact replacement? My T4XC works fine)

Paul,
Do you want to trade just the knob or the knob and skirt? I have a knob with the flat skirt that I would trade for a knob like yours but would it would have to include the "rounded" skirt like what was on a R4B.

HI Lawrence,

Not sure I understand. The skirt I have is not flat, it is sort of beveled "back" toward the radio. So I guess the knob itself sits about 1/4" off the front panel. (You can see a picture of my R4A on the PHOTOS section from an April 6 picture, I have a KNOB with black finger dimply or stainless finger dimple).

Would the knob you have FIT, or would I require to have a flat skirt? I want to keep the rounded skirt that I have currently. Are you saying R4A skirts are flat and R4B/T4XB skirts are "rounded"?

paul

Topic: 20957 Message: 20957

Ok, reading these comments on the VFO knob skirts got me to looking at mine.
I noticed a while back that the one on my R-4B was a little different from the one on the T- 4XB.
The are both conical but the one on the receiver only has lines on it and the one on the transmitter has lines and numbers. Its not a big deal but since you got me to look at them I thought I would ask if one has been swapped out or something?

Paul -

Your T-4XC also uses a 6EV7, NOT a 6EJ7.

I think you have rebuilt your power supply, so the BIAS voltage should be stable.

'Sticky' relay like this usually indicates a leaky 6EV7. Could also be a bad D9 or D12.

Check the voltage on C99.

Check the Grid voltage on Pin 7 of V10b and see if it changes when 'sticking'.

You can also reduce the value of R94 to 470k.

rochep@... [DrakeRadio] wrote:
> I have read that a T/R relay that starts out fine, and then gets worse as your TX warms up(sticks for longer and longer time and eventually NEVER releases to RX) , is a sign of a gassy 6EV7 VOX tube. I have that problem. When I first turn on my TX I can tune up, all is fine, and maybe a quick DX "5NN" contact. But after 3 minutes or so, when I key the rig it stays in transmit. Have to actually turn OFF the power to get it to trip! Happens in dummy load; I can simply close my PTT switch, NOT actually send code, and when I release PTT it does not open the relay.
>
> I have now bought TWO "new" 6EV7 tubes, no cure. The T/R relay setting seems VERY sensitive to the vox gain/anti-vox/vox delay settings. I like a VERY quiet sidetone: I tried increasing it and does not help. Am I perhaps setting up the rig wrong, or should this type of behavior really a sign of yet another bad 6EV7?

The one with just lines may be from a TR-4. The "B" skirt is 'dished', and has 0-25 (kHz) markings. the "C-Line" skirts are dished with no lines or numbers.

Re-check you bias when "cold" and then after the relay starts to stick. It should not vary. A gassy V13 can also affect the bias.

Just my 1 cent worth.

No, but if the tube is 'marginal' the amount of bias shift tolerated may be less. Most power
handling tubes suffer from a 'little' grid emission. If multiple tubes perform similarly, it's
'possible' that you have had 'bad luck', and again power handling tubes are 'gas' prone as well,
so ...

The tube is supposed to be biased off by the negative voltage applied to the grid of V10b via
R94 to cut it off in STANDBY. When the SSB audio or CW sidetone is rectified by D10 and
integrated in C99 to develop a positive voltage to shift the Grid positive and cause V10b to
conduct. the ANTI-VOX audio has it's positive level clamped by D12 and rectified by D9 to apply
a negative potential to the Grid, offsetting the shift from C99. A bad D12 allows D9 to go more
positive, etc., etc.

So to answer your question, yes, a short warm-up before failure IS typical a of 'gassy' tube.
However when I get this from two 'new' tubes in a row I like to check other possibilities before
going and buying a sleeve of five 6EV7s! :-) And yes, this fault is hardly ever noticeable on
a tube tester........

Gary -

The R-4A had four distinct versions. Two of the Early (13 tube) type and two of the Late (11
tube) type. The crossover between types was at s/n 4054. I believe only the first version came
with the 5 kHz dial markings and vernier PreSelector from the factory. There were approximately
1,000 units of each of the first three versions built, and about 1,600 of the last version.
Production ran from November 1965 to July 1967, about 18 months.

20970. TR-7 success

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-14 18:43:26 UTC
From: geoffrey mendelson
Topic: 20970 Message: 20970

I'd like to thank everyone for their help and encouragement. I tackled the TR-7 today.

So far:

1. I unjammed the PTO. The dials are off by about 100kHz, but with the DR7, I don't need them.

2. I replaced the light bulbs (one an odd miniature bulb soldered in place) with LED bulb replacements. No more taking the radio apart to change bulbs.

3. I went to do the filter mods and found that it already had 1800Hz, 500Hz and 300Hz add on filters.

4. It has the noise blanker.

I've tested it into a dummy load and it seems to receive, the frequency and noise changes as you tune the dial, and it transmits when I speak into the microphone on LSB and USB.

Now I have a question.

It does not seem to cover an entire ham band at one time. For example, 14.150 is near the high end of its band, 14.250 is at the low end of the next band up. Is something wrong, or is it supposed to work this way?

TIA,

Geoff.

Geoff -

The little lever on top of the PTO releases the gear train so you can set the dial to the correct reading.

You should be able to hear the CALibrator signal every 25 kHz.

It tunes the 1.5-30 MHz in 500 kHz blocks. If you set the BAND switch to 14, you should be able
to tune from 14.000 (0.000 on the dial) to 14.500 (0.500 on the dial) MHz. The only band that
is split is 10M, which sets to 28.5 MHz, and the UP or DOWN buttons are depressed to move it 500
kHz at a time to cover the rest of the band.

I can't think of any way offhand to get 0.250 at either end of a range, so you may have a divider problem. Maybe Jim or one of the other TR-7 experts will check in on that.

Lee,

Thanks for the clarification, I was not aware that that existed. I have 8 or so AC-4 supplies and never noticed that change. I have noticed that one change, owner modification, was to drill a row of horribly aligned and shaped holes and then an fan placed loosely inside the cover.

It never ceases to amaze me what people do to these things.

Thanks,

These are LED bulb replacements. They look like a #47 bulb. They have a bridge (so they can be used on AC) and current limiting. The ones I used in my SPR-4 are 6 volt and work fine in series with each other or a resistor. I put 12 volt ones in the TR-7.

I got mine from superbrightleds.com, You can also get them from cointaker.com and 2bradioparts sells 6v ones. Possibly eBay direct from China, but I did not look.

73.

Geoff.

I thought I would tell the gang what I discovered tonight. I don't have the CD for the T4XB, so don't know where C99, D9, or D12 are located. Oh well ... ...

But what I DID find was this:
I tune rig on 40CW into dummy load. On SSB setting (relay OPEN) I read -3.8V on pin 7 of V10. On TUNE (relay closed and transmitting) I read -0.6V on pin 7 of V10. When the relay gets STUCK (hung-up) in CW mode (when NOT keying the rig) I read -2.9V. If I now KEY the rig it goes to -0.5V.

Changed V1 for a good 12AX7, that seemed to help!! Also changed out 6EV7, but in my flipping over and back I re-set all tubes in radio and ... BETTER!!

I ALSO noticed that after 30 minutes of warm up my bias was NOT 70 mA, it was closer to 100 mA. So I re-adjusted it. Seemed fine, so I took it off the bench and hooked her up for some QSOs.

All was going well using my bug for some QSOs, relay dropping in and out as expected. Then I got greedy. I made a PTT footswitch with the mic cable, and when I hold that down during a QSO (to avoid relay clicking after every word) STUCK!! Seems like when I keep the PTT closed, when I then release it I am STUCK! To verify this is true, I had ANOTHER QSO and did not use the footswitch, no problems.

When the footswitch is actived (relay closed) and not keying the rig the resting plate current is about 100 mA. Why would it get "stuck" simply because PTT is down for a "long time" (when I click and release PTT quickly all is fine, it seems to be bad when I HOLD the PTT down for 15 seconds or more).

FWIW, the 44/47 LED replacement lamps from cointaker.com hava a small internal resistor that lets it's smoke out with overcurrent. The lesson learned from this is to put external resistors in series with the high side of the socket. It's only too easy to accidentally rotate the socket tabs (in the 7-line) and ground out the low side to the chassis...

I have R4A SN 2050; date of mfg 12/31/65.

It has the 5 KHz markings and the vernier preselector.

Good radio. I am second owner. Have had it since 1980 and still works
great!

This is where a properly calibrated analog dial would be helpful... :D Check with a frequency counter or another reciever to ensure that the PTO is on the frequency that it should be for the reading on the display. The formula is the same one that is used for selecting fixed crystals for the AUX-7:

Freq. (kHz) = 5050.0 kHz + Desired Carrier Frequency (kHz) - Lowest Range Frequency (kHz)

I.E., for 14.250 it would be 5050 + 14250 - 14000 = 5300 KHz

Obviously at the bottom of each band it whould be 5050 KHz. The top of the band should be 5550 KHz. You should find your PTO within a few KHz at the most of the expected frequency. There will be a couple of hundred KHz of overrun at each end before you hit the stops, I can work down to just below 28.300 in the 28.5 band segment on my main rig. If the DR-7 and the rest of the rig electronics are working properly you should be able to hear a known signal at it's expected display frequency. WWV at 5 or 10 MHz would be a good choice if you can hear them where you are.

If the PTO frequency shows up where expected from the display reading and you can hear a known signal at the display frequency then you have a problem in the PTO, I'm guessing mechanical. The PTO gurus here can help you with that. If not, tune to a known frequency by figuring the PTO frequency required to get there and see if you can hear the signal. If this works OK there may be a problem in the preset decade counters in the DR-7.

If neither of these meothods produces reception of a known singnal I will have to think about it some more....

Thanks. I bought mine from superbrightleds because cointaker did not
ship here when I was buying. I bought both 6 volt versions, which I have
successfully used in the SRP-4, and for Ten-Tec radios the 12 volt
versions. In some radios Ten-Tec just connected the bulb directly to the
12(13.8)v power line. Since I had them when I got the TR-7, I used
them. I would not dream of using a #47 on 12 volts, and the same for the
LED equivalent.

Thanks. I was thinking of it last night, and the best thing I have is an MFJ antenna analyzer. Not particularly stable, but a calibrated signal generator nonetheless and a frequency counter.

I figured before I started doing such things, I should keep some record of what actually is happening and before breakfast I tried to tune in the 20 meter band. I started by moving the band switch and coming back to 14mHz, and found that from the point where it makes bad noises and I know to stop, the PTO goes from 13.7 to 14.6 mHz (and slightly beyond), so I expect that it was either a dirty connection or operator error.

Hopefully at this point, this will be the last repair question for a while, what is the threading of the set screw in the main tuning knob? Mine is missing.

TIA and 73,

Geoff.

Cointaker did not have 12V versions of the warm white, so I used the 6V version with an external dropping resistor. Works fine (except for the aforementioned incident after I put the resistor in the low side on one just because it was a bit more convenient). As for never replacing lamps again, well..... LEDs have a lifetime. If you own the rig long enough you will have to replace them. I've noticed that the warm whites seem to have dropped somewhat in brightness just since I put them in.

But they will last a lot longer than the original lamps.

I think it was you who also asked about the serial number. I seem to recall hearing somewhere that Drake also stamped the serial number of each rig on the inside of the front panel.

I've mentioned in the past a "poor man's AM filter workaround", how to modify the radio to get useable AM reception from a TR-7 without a filter.

Looking at the filter board of my TR-7 I found it already had 3 optional filters, and there is no room for a fourth. This was a "let them eat cake" disappointment. I could not call myself (at least in filters) a poor man, nor could I listen to AM.

I remembered an old trick from a Kenwood rig I had, if you turn the passband tuning all the way to the right, you get readable AM. Actually quite pleasant.

Paul -

Well if you don't have the CD, you deserve whatever happens to you!! :-) The diodes and C141
(not C99...) are located on Board 4, right next to V9 and V10. C141 is the film cap usually
either black or yellow. D5 is right along the top edge of the board next to C141, and D9 and
D12 are down near the middle of the same board.

This is just a guess, but perhaps you are seeing the result of gassy PA tubes. The BIAS supply
is only supposed to see a 33k ohm load. That's only a couple of mils. So it doesn't take much
to 'load it down'. This would cause the IDLE current to increase, which you are seeing. It
would also reduce the negative bias available to cut off the 6EV7, which you are seeing. This
is why V1 has an effect.

I don't know the condition of your PA tubes, but they are the most likely source of grid
emission, especially since it seems to be related to the 'on' time of the PA. (relay closed)..
Of course the 6EV7 is the most likely suspect and you should check the BIAS voltage when the
6EV7 grid voltage is low also. If the BIAS 'bus' is staying steady when the 6EV7 grid is low,
then you know it's a gassy 6EV7. Grid emission is exacerbated by heat, typically after 5-10
minutes in receiving tubes, but power tubes are more susceptible.

Don't forget, NOS tubes are not always good tubes..... Real Gassy tubes can result from air
leakage past the glass metal seals. Grid emission is usually the result of age or mistreatment
causing Cathode coating flakes to dislodge.

Geoff -

This is known as 'exalted carrier' AM..... Tune the signal for zero beat on the carrier, and
then choose either sideband to listen to. ALL the information is duplicated in each sideband
anyway... :-) A benefit of this method is that the receiver bandwidth is less than half of what it is in AM, so lower noise and improved interference rejection.

A further benefit is that signal loss due to fading of the carrier is reduced, since the BFO is
always there. So you only have signal loss when 'your' side band fades. Yes, the sidebands and
carrier fade 'separately', i.e., one sideband, then the carrier (sounds like SSB), then the other sideband.

I certainly do not know if these PA tubes are good. I have a "bad" set of PA tubes that go into oscillation if I tune up and up and up and I get TONS of output (about 150 watts), but I could probably try the "bad" PA tubes in the T4XB (keeping output at 90 watts or so) and see if I have the same "hang-up problem" with a different (albeit not perfect). That might help narrow this down to PA tubes. But if it is the PA tubes, I would think the "problem" PA tubes put into a working T4XC would also cause the TX to hang up. (or maybe not)

I want to make sure I understand what you mean when you say "BIAS supply". Is this the -50V or so coming out of my AC4 (this is set with the bias pot on the back of the AC4)? Are you saying that the "negative voltage" coming out of the AC4 should ideally be DIFFERENT my rig is in standby (with relay open), when relay is "stuck" but no RF out (relay closed), or when I am transmitting? That would be easy to test. I would just hook my DMM to where the bias comes into the rig from the AC4. Is that the "bias bus"; how "steady" is steady? How should it change under normal conditions?

Of course, it is also possible that BOTH sets of finals are "gassy" as are my 6EV7 tubes. And I think I understand you saying that holding in PTT keeps the PA on, and that heat might be a problem. Working semi-break in gives LESS time for the PA to be on, so less heat and less grid emission?

Paul -

Any time the relay is closed, the PA is dissipating IDLE current. Since heating seems to have
such an effect, (between semi-breakin and PTT,) it sure sounds like grid emission.

The BIAS supply is the -60 VDC coming into the T-4XB from the AC-4. I thought you had 'rebuilt'
the AC-4?? I've got three different T-4XB 'projects' going at the moment and I'm having trouble keeping them straight....

The fact that the IDLE current on the PA tubes increased that much makes them highly suspicious. The PA tubes put into a T-4XC may or may not work the same. The circuitry is different in the two.

Turn the transmitter on 'cold', set the idle current and then measure the BIAS supply at the
connector and at the second feedthrough from the front on the PA shield. The one with the 1.5k
resistor on the inside. Then let the transmitter heat up, transmit into a dummy load, for 15 -
20 minutes or until you see the IDLE current increase, and then measure the connector and feedthrough voltages again.

Thanks for the info guys. After owning Drake gear since the early 1970s, I was totally caught by the reference to a double slotted AC-4. So I learned something new! When I get home I will check my spare AC-4s. I am sure that all are double slotted but will look.

From: Ken DeBower
Topic: 20992 Message: 20992

Greetings to the group. This is my first post.

I'm resurrecting a very ugly T-4x. After cleaning the chassis and contacts, and replacing one 6JB6, it works pretty well. The chassis is covered with rust and looks terrible, though the front panel looks good. The poor thing was stored in a carport for years and took quite a beating.

Now, my questions concern matching PA's.

I replaced R32 and R33 with 14.6 ohm resistors and installed two matched sylvania 6JB6's from rfparts.com. Adjusted bias and found approximately 35 ma and 20 ma plate currents by measuring voltage across R32 and R33. Clearly not matched. Not even close. Swapped tubes/sockets and got same results. So my first question is: Should one of these tubes be considered bad or are these variations normal and I just have a bad match?

Next, I paired the higher reading sylvania with one of my originals (the other original is clearly bad), adjusted bias, and now have 38 ma and 31 ma. Not great, but power goes out the antenna: 100 w on 80m and 20m, 60 w on 40m, 15m, and 10m cw. Second question: Might I adjust either R32 or R33 to get matched idle currents? Or would that just introduce new problems? It looks like it would take significant adjustment to get these currents to match.

Finally, assuming adjusting R32 or R33 is not a good idea, is the best course with these tubes to simply reduce power and transmit?

Many thanks to all posters in the group. I have learned much, and have much to learn.

Hi Ken,
Check the screen resistors on the finals, too. They often drift of value like the cathode res. They will affect the plate current. I wasn't clear on when you swapped tubes, did the readings go with the tubes or stay with the sockets? If they went with the tubes, then it's a tube problem. I think the difference, if it goes with the tubes, is significant.

Hi Al, thanks for responding.

The problem went with the tubes. Independent of sockets.

I'll take a look at the screen resistors.

Guess I'll try to return one or both tubes.

Any thoughts on forcing idle matching currents by adjusting cathode resistors?

Ken

Al,

I looked at your Drake webpage, saw your R4A receiver serial number 6850G. My R4A, serial number is 6829G, very close to the same run as your R4A. I'm not the original owner, I purchased the R4A recently from Paul R, I think he's a member of this group. It had a bad power transformer, Paul and I both knew that, so I replace it with a new, not rewound, power transformer from Hayboer Transformers out of Grand Haven, Mich for $80 (see link below). The plate resistor in the pre-mixer stage was cracked in half, just barely making contact, causing reduced receiver gain. Replaced the resistor, the can cap and a few other electrolytic caps from Hayseedhamfest plus the power transformer and the receiver started working quite well. The alignment was off a bit, mostly in the Bandpass adjustment. Once that was taken care of the receiver works great. The new transformer doesn't have the dual primary winding so the receiver can only be powered from 120VAC. I made a note of that in the manual so any new owner, if I decide to sell it later on, will know.

Just thought I would comment about that.

20996. tr-7 tuning knob setscrew

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-15 20:52:02 UTC
From: geoffrey mendelson
Topic: 20996 Message: 20996

Anyone know the specs for the setscrew in the tuning knob of a TR7?

Seems insignificant, but I have no other way of getting one except asking someone I pay to do these things, so it is easier and a lot cheaper to order it from eBay. :-(

TIA and 73,

Geoff.

the best thing I have is an MFJ antenna analyzer.

Geoff,

NOT true, you have a fine frequency counter, its called a TR7, to 150 MHz
You can feed it its own PTO signal.

Hopefully at this point, this will be the last repair question for a
while, what is the threading of the set screw in the main tuning knob?

If you don't get an answer I will pull a knob and measure the thread.

Geoff.
Try 9/16 inch long, slotted, 32 TPI, and I believe a # 6.

I am sure Garey will have more authoritative
information but I will give this a shot. I have a T4XB, not
an A but I think they are similar. The screen resistors are
there for decouping the screens and along with the small
value capcitors isolating them from the screen voltage
supply. They do not set the screen voltage, that is set by
the large higher value resistor in series with both tubes.
The resistors should be about the same value as should the
cathode resistors be about the same value. None of these
resistors should be varied to change the cathode current,
the output stage will not operate correctly.
The cathode resistors do not set the bias, that is set
from a negative supply connected to the control grids. Both
tubes are supposed to operate with the same voltages on them
as thought they were one larger tube. The idea of matching
is to insure that one tube does not carry more than its
share of the output power.
Assuming the cathode resistors are matched in value you
can measure the relative cathode current of the tubes by
measuring the voltage drop across each. This value will be

the same if the tubes are matched. The matching is really for a number of tube constants, mostly for mutual transconductance or Gm. The tube constants are determined by all sorts of things; the condition of the filament being very important but also the tube is sensitive to very small variations in the geometry of the elements and small amounts of gas and other things. If a tube has been worked hard or overloaded the filament output can be reduced. A tube with a tired filament will have low plate current when the voltages on all electrodes are correct.
If the tubes have different cathode current and the current follows the tube they are not matched and if there is a lot of difference something is wrong with one or both of the tubes. You may be able to determine this by comparison with several other tubes but of course the best way is to measure the tube on a good tube tester. Unfortunately, not many hams have tube testers at least those set up to check compactron tubes. The in place measurement of cathode current with a comparison to a couple of other tubes is sufficient at least to tell you if you have some bad guys.
There is been considerable discussion in this list about tubes that can be used in place of the 6BJ6, at the moment (its past my bed time) I can't think of the ones usually recommended but someone here will remind us. These tubes are generally cheaper and more easily availble than the 6JB6 and require only re-setting the neutralization.
Note that the voltages and currents are those at which the final amplifier will deliver _low distortion_. It may be possible to get more power out but the quality of the signal will become degraded. The distortion in an RF amplifier is not quite the same as in an audio amplfier, its not audible as distortion but produces spurious signals near the desired one. Of course they can also make the transmitter sound bad but will be causing QRM before that happens.

David -

This is normal. Remember how TUNE works.... A 1 kHz audio tone is applied to the BAL MOD, just
like whistling into the mic..... So a double sideband signal comes out of the BAL MOD, and the
desired single sideband is chosen by the filter selected.! CW and AM are done by shifting the CAR OSC into the LSB filter bandwidth and the BAL MOD is unbalanced to allow it through, and
then it goes on through the LSB filter. So for these modes, the LSB (X-) filter must be chosen.

The TR-4 does it differently. There the TUNE mode is accomplished the same way CW is done in
the T-4X(any), so here the LSB filter (X-) must be chosen.

Interesting...
So there really must have been 3 early (13tube) versions of the R4A:

1. 5KHz markings, NO vernier. This is the one I had "back in the day", don't know what serial it was.
Was a ham store demo model sold off after a time, must have been a really early one.

2. 5KHz markings, vernier. Like you two guys have.

3. 25KHz markings, vernier, like I have now, (since 1980).

Ok then, I was just wondering because it was something I wasnt sure about. (The tune signal)

I received my AC-4 bebuild kit today so Im working on the power supply now.
Ill get back to the rig later but on the neutralizing, I checked on 40M and 10M and it seemed to be ok. The power dropped of on either side of the dip. Those tubes are different but they almost had the same Gm and one drew .06 ma than the other. I have the other set coming but I dont think they will work any better.

"note for the group"

I still need to get some parasitic suppressors for the T-4XB if anyone has some they can sell, one broke on me.

21005. Checking Bias across R36

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-16 23:10:50 UTC
From: rochep@...
Topic: 21005 Message: 21005

I am not afraid of embarrassing myself in public, so here goes!!! I am not sure I am "measuring the voltage drop across R36 to set the bias at 70 mA" in my T4XB.

1. I am using a DMM, not a VTVM, but anyway... I am NOT simply hooking one end of my DMM probe to one side of R36 and the OTHER end of my DMM probe to the other side of R36 and then looking at the meter when I flip the FUNCTION switch from SSB to TUNE.

What I am doing is this: There are TWO ends of R36, I will call one end the FRONT and the other end the REAR (as I look at the resistor). I measure voltages on each probe in both SSB and in TUNE (gain at minimum).

FRONT end SSB setting >>149.2 V and FRONT end TUNE setting 227 mV
REAR end SSB setting >>149.1 V and REAR end TUNE setting 10 mV

So the difference in the TUNE setting is 227-10=217 mV. With 3.3 ohm resistor >> 66 mA.

Am I doing this correctly?

paul

Your in the ball park at 227. Measure directly across r36 I think is the simpler way. -70ma X 3.3ohm is 231mvdc.

Clips of your DVM should go directly on each side of r36. Turn the bias till you get 231mvdc give or take.

Dave :)

All this R4A talk got me looking at my R4A. I got an "authentic" R4A knob/skirt from Lawrence (in this group). (I have just posted some pictures in the PHOTO section). But I notice the skirt sits about 1/4 off of the faceplate when pushed back as "far" as it can go; it can not go back any more because of that cotter-pin you can see in the photo. (the U shaped tension washer moves back toward cotter pin in use). Is this what ALL R4 shafts look like, it is "normal" for the skirt to sit that far OFF the face. Is this why they make the "slanted" skirts for the R4B/C??

Thanks Dave,

I told you I was not afraid to be stupid!! I thought maybe if I directly went across R36 something bad would happen. (That's what you get when you really don't understand electricity).

I know I can also make these measurements ABOVE the chassis. So when GASSY final PA tubes make the bias go up in value, I can see this as an increase in the voltage across R36? After a 5 minute warm up, what is an "acceptable" increase in voltage across R36 over (say) a 30 min period of time? Is an increase from 70>>72 mA tolerable?

paul

From: rochep@...
Topic: 21005 Message: 21012

I set BIAS to 231 mA with 3.3 ohm resistor for 70 mA after 3 minute warm up.

Then I wanted to see how stable the BIAS is in TUNE:
in TUNE for 30 seconds went from 255 mA to 278 mA, another 30 seconds and it went up to 300 mA

(I guess BIAS increased from 231 mA to 255 mA between setting it and beginning experiment).

Then I let PA tubes cool off in SSB mode and repeated experiment:
in TUNE for 30 seconds went from 250 mA to 256 mA, another 30 seconds and it went up to 271 mA

Is this an example of me setting the initial bias too low and then gassy finals increasing the bias over time? I am trying to figure out a problem with sticky T/R relay and some ideas are gassy finals and problem with BIAS.

Paul

Stupid is not trying ;)

I'd let the radio warm for 30m before adjusting the bias. Then after you adjusted tune it into a dummy load at full power say on 10m. Then let it ideal away not in TX and not in TUNE just power on for another 30m. Then tune again into a dummy load one more time. Now in ideal check your r36 it should be still around -70ma or in your case around 231mvdc.

If your tubes have Gass then hopefully that will get some out. Your tubes are they old or NOS tubes you just installed?

Hi Gary, thanks for the reply. One of my ms-4 speakers has the w4 watt meter in the grill. I was told it probably was a prototype from the 70's. Only the meter and components are mounted in the grill, not the whole w4. It also has a factory plate under the meter for 200-2000 reverse and forward settings. I sent a picture to Ron baker and he said it was professionaly done. But he wasn't sure if it was a prototype. I did add the ms4 emblem to the grill. At any rate, there may only be a very few in existence, and it is also as close to mint as you can get. Maybe other drake collectors have seen or heard of one. I can send pictures if anyone is interested.
Thanks again Gary , Dave. W6dst. "73".

OK, I'll do this. Maybe I have been setting the bias when the radio really wasn't warmed up. The tubes are the ones that came with my T4XB. I don't really know what "gassy" is, but do you mean I can actually " let the gas out" and they will be "better" (not gassy anymore). I thought gassy was a defect and once gassy always gassy? (sort of like my grandfather was; different kind of gas I think).

Well yes and no some times running tubes for an hour or so will work (and thats controversial) however we need to make sure you have that radio nice and warmed up before we can make a determination or valid adjustments. I'm know expert with this radio and with that in mind let's first find out were we are with the radio warmed up bias adjusted and if were getting full power on 10m :)

I believe you are correct, the R-4 didn't have the vernier, and I think it was added VERY early
in production. I've never seen an "A" without a vernier, but seems like a vague memory is trying to push out! :-) It would not have surprised me if Drake hadn't switched over the the
"A" and had a few early ones 'left over'. Drake was pretty good about responding to user's suggestions.

The R-4 actually worked ok, and was really faster changing bands, but needed a little 'safecracker's touch' on 10M! :-)

IF the idle current drifts up after 5-10 minutes or more, it's probably 'Gas', or probably in
this case more accurate to say 'Grid Emission'.

Small flecks (chunks) of Cathode coating material flake off due to mistreatment (off resonance
operation mostly) or just overload, or even just age. These chunks stick to the Grid of the tube, and as it heats up, (beyond 'warm-up',) they get hot enough that they start giving off
electrons as well, which go to the Plate just like the rest of crowd. Those electrons leaving
drive the Grid more positive, increasing whatever the set idle current is. It is a snowball effect, and in some cases can result in the Grid losing control entirely. Mostly this occurs
within 5-20 minutes, whereas a resistor or other component heating up will happen faster than
that, and almost always 'run away' or snowball producing smoke.

We see a similar effect in the 12BA6 especially, in the IF of the 4 Series receivers, where the
S-Meter is set to zero at the start, but then 'drifts' up (Or down) over the first 10-20 minutes
of operation, depending upon which tube is 'gassy.

I've followed the directions in my owner's manual. Adjusted the AC4 pot to get about .07 plate current. Put the radio into Tune, adjust the RF Gain about one mark.....I followed the instructions to the letter but the meter never goes above that .07 mark. I can't "dip" the plate current so I can't go any further. What am I doing wrong? I'm very new to old radios and not much of an electrical techie type. These B "Twins" were given to me, along with the power supply/speaker and an antenna tuner (also an Astatic D104 mic). The only HF radio I've ever used is my Icom 718, and I've only been on HF since Feb of this year. I'm very new. I've tried searching Youtube for an instructional video but came up empty. Can anyone help me?

OK Dave, Here goes. I've been at this most of the night.

Turn on T4XB at 10:00, at 10:15 pm set bias to 231 mV.
At 10:30 Tune up on 10 M CW max 178 watts input/100 watts out >>55% efficient. Not bad. Bias is now 237 mV. Not too bad a drift for 30 min. Put TX in standby (SSB)
At 11:00, re-tune on 10M (all settings stay about the same). Now 169W input/93 watts out >>55% efficient. Still good. Now bias is 250 mV. Crept up more than I like, I now re-adjusted it to 231 mV.

Since I USE the TX after about 10 minute warm up, I should set bias based on this. My bias MIGHT creep up a bit with these PA tubes, but no so horrible.

And 100 watts out on 10M, pretty good.

Jared -

Welcome to the group!

I think you'll need to turn the GAIN control up to about 10 o'clock to get any drive. BE READY
to dip the Plate!! More PA tubes are destroyed by failure to KEEP the Plate dipped than any other factor. Start with the LOAD control Minimum, full CCW.

The key to long PA life is 'Dip the Plate, first, last and always'.

Best to start on 40M as adjustments are a little less touchy there until you get a feel for it.
Once you get it dipped, increase the GAIN to about 11 o'clock. Then increase the LOAD control a
little CW, the plate current will increase, dip it again immediately. Repeat until increasing
the LOAD control further CW or until the DIP at minimum is around 340 mA.

If you have an output meter you can follow the above and just tune PLATE and LOAD controls for
maximum output. Dip the Plate.

Hi Garey,
Yes, this is a re-built AC4.

I did what you said with the BIAS supply voltages.

When COLD:
at connector is -53.8V in SSB and -53.3V in TUNE.
-51.6V at feedthru (one side of 1.5K resistor) and -51.4V on TUBE side of the resistor

When it gets HUNG UP:
-51.0V at feedthru and when relay releases reads -51.7V (just like cold)
-50.8V on TUBE side of resistor and when relay releases reads -51.5V (just like cold)

Does this tell you anything (other than to really know WHAT is happening I have to cough up $70 for a matched pair of 6JB6 tubes!).

Sure sounds like finals. You'll notice when the relay hangs up that there is a full volt drop
across that resistor. I suspect it would only increase with further 'heat'. There should be zero Grid current, but obviously there is some even when cold.

I have to admit I've never thought about this, and may be off base, but it sure looks suspicious
to me. Another key to me is that I find the BIAS voltage for a good set of finals to be closer
to -60V than -50V, which indicates the tubes need a little less BIAS to run IDLE current.

You could try ONE tube at a time, in the same socket, and measure the idle current individually. This might show one tube is in worse shape than the other, which would increase
confidence in the result. Or they could both just be equally 'soft'.

If cost is a concern, you could use a couple of 6GJ5s. You could buy six of those for less than
a 'matched pair' of 6JB6s and make your own 'matched pair(s)'. As long as you stay with the 'big 4' brands, they work as well as 6JB6s. Some seem to have problems on 10M, but I've not run into that yet. Try to get all of one brand, as the chances of matched pairs are better.

You have an 'extra' circlip on the shaft. The guy who swapped the knob added a circlip to move
the knob out away from the panel. Most of us just moved the 'original' one out a bit.

By the way, those clips WILL break!! (Ask me, just ask me.....!) You need to use circlip pliers (auto store, $5) and only expand it enough to slide off the end of the shaft. SAVE it,
as those are just about impossible to find. They are MUCH stronger and heavier than you find in
the typical auto/hardware store.

So remove the extra one, and you'll probably find the original is in the right place. If it puts the knob too close, use your circlip pliers to move it out enough to clear.

This "extra" clip is in exactly the same place as the "extra" clip on my T4XB. Yep, if I can just shove it back a bit (so it will give the C-washer something to "push" against) that will be great. I assume "regular" pliers or a screwdriver won't do the job. Hate to pay $5+ for something I'll use once.

Am I correct in thinking this is NOT in a groove in the shaft, it is just "pinched" in there?

Paul -

OK. $5 will sound cheap after you break it!! No groove, just really tight! Obviously you can't just 'shove it' back, kinda defeats the purpose..! :-) You need a tool with two 'pins'
that you can put in the holes in the circlip. You need to apply _very little_, _controlled_ 'outward' pressure to expand it just enough to slip. Just a little too much pressure, and it
will become a two-part item, both of which will disappear. I'd also suggest safety glasses, even it they do cost a buck or two..... As Joe said, they REALLY fly, and when they break......

Granted, I AM a 'right tool for the job' kinda guy, but ....

Those little holes on the circlip are REALLY tiny. Will the "pins" on those Harbor Freight tools really fit into the little holes in the circlip? Or do I just use the "pins" on the tool to wedge between the opening and then squeeze to "open" them a bit? I intend to get the right tool.

Paul....

I think the pliers come with various sized 'jaws', to work in any circlip.
My circlip pliers are 50 years old, from my days as a wrench.....You will
need to go to a store and look to find out for sure.

Whatever you find please post the results here. I had a nice circlip plier that worked fine on an SPR-4, and a set from DX.com that I expect is the same, or very close to the Harbor Freight set. Neither was small enough for the dial mechanism on my TR-7.

Suffice it to say a new clip (part of an assortment) is on the way, but I have no pliers to put it on. I probably can push it on without a set of pliers, but I am afraid that will be a one way trip. :-(

Geoff -

I couldn't find a suitable clip anywhere... I tried several assortments, and they all had the
right size for the shaft, only about half as thick all over. I could put them on the shaft, but
they wouldn't even stand up to knob pressure to compress the clutch tubing. The one Drake used
must be a heavy industrial type, perhaps someone like Grainger would have them?

So yes, you can probably just push it on, but .... :-)

Paul the eBay set is identical to the one I have, and works fine. The smaller pins go into the
holes. It 'MIGHT' work the way you describe, but you need very controlled pressure, and you
have to be able to push the clip along the shaft while applying just enough!

The look like the ones I got from DX.com which means the pins are too
wide to fit the circlip in the TR-7.

It's also being sold with that "global shipping program" scam, where
they charge you $35 to ship it to a mail forwarder who mails it to you,
but you can't tell what the total postage would be until you buy it.

If it were sent via the US mail directly it would cost about $12. There
is about a 2% "loss" of packages sent by the USPS, but if you read the
fine print, since the eBay seller ships it to a third party in the US,
they don't have to cover any lost packages.

Richard:

Wow, thanks for all this. You have exactly answered, clearly, many of the questions that were swirling around unformed in my head.
Substitutes for 6JB6 I've found include 6JU6 (not so good), 6GJ5 (pretty good), 6146 (big job), and possibly 17JG6. I like this last best, tubes are inexpensive and a simple transformer could supply filament voltage.
This old girl (T-4X) I'm working on will never win a beauty contest, what with all the rust. So I don't mind adding a few things to get her to work.
Again, many thanks.

Just a thought to get you by, why not use a pair of them? If two is to thick you can emery them down to fit the groove. Rough on the finger tips but two may stand up to the pressure. You might be more able to find a jesus clip to fit the groove and work for now. The difference being, what you have is a snap ring with holes for pronged pliers to fit into for installation and removal. The jesus clip doesnt have the holes, it just snaps in and then when you take it off you never know where the heck it flew off to. You have to be very crafty to take one off and keep it. I dont know if you are wanting something to get by or forever right now.

Ken -

I recommend against the 6146 mod. I've built and used many transmitters with one or two 6146
tubes, and it's a great tube.

The Drake T-4X(any) however is not well suited to them, too much VHF and up gain. The plate voltage is low, limiting 'clean' power, but most importantly no-one has ever done a thorough
evaluation of the amplifier using them. The parasitic suppressors almost certainly are not right, and the rest of the PA is designed around the 6JB6, or at least another 'similar' high
perveance sweep tube. Plus the 6JB6s cost about the same and will last just as long. The weakness of the 6JB6 is the same feature that makes it suitable for this power at this HV level.

The 6GJ5 works just as well as the 6JB6, if you stick to the big 4 brands, and neutralize them
properly. The 17JG6 is interesting, never ran across that one. There is a 17JB6 and a17GJ5 as
well in the same price range. I wonder if a voltage doubler on the filament supply with a regulator ...??? Maybe a tripler and leave the tube filaments in series. ?? Probably easier to put a small transformer in the AC-4 and keep the PA filaments in series, 0.450A current that
way. Interesting thoughts for if/when we run out of 6JB6 and 6GJ5... :-)

Most of the answers can be found in the Eimac publication "Care and feeding of Power Grid Tubes" issued in several editions all of which are available free via the web. Not quite the latest is at::w5jgv.com/downloads/Eimac-pwr-grid.PDF but this one has the answers in it.
In fact, one can have individual grid bias adjustments on the tubes. This is usually done on high-power amplifiers and may be necessary when running at Class-B or near it because the bias becomes very critical and very small differences in the tubes will result in a large difference in idle current and performance. I don't think it can be used to compensate for large differences in tubes because even if the plate current is made the same the variation in current with grid voltage will not be matched, that is, the tube curves can not be made enough similar. Large variations between tubes usually indicate some problem with one or both tubes. It might be possible to compensate some differences by having individually adjustable filament voltage, again, this is found in some large amplifiers. For something like a T-4 one is really stuck with finding tubes that match each other fairly closely.
Another subject in the Eimac book is a good explanation of the various "classes" of tube operation which will help to understand the need for matching and how closely the match has to be. I believe (Garey can correct me) that the amplifiers in the T-4 series Drakes run Class-AB1, that is, they do not draw grid current. This is a fairly forgiving operating condition.
There is a lot to be considered in the operation of linear amplifiers beyond just power output. Probably keeping third-order distortion (that is intermodulation distortion) at low levels is most important along with not exceeding the tube limits. One can always get more power out if distortion is of no concern. I think drake chose operating conditions

that would keep distortion at a reasonable level despite some degree of misadjustment. The ALC prevents overdriving, I think it prevents grid current or at least keeps it below some limit. Excess grid current will kill tubes very quickly beside causing distortion to climb. Drake has done a good job in making a pretty reliable transmitter with a lot of protection from misadjustment although you must still be careful not to exceed plate current when tuning up (keep the plate dipped!!). Drake specs are very good(compare to Collins S-line) and will meet them without a lot of fuss.
I think modern solid state transmitters with all automated tuning have spoiled a whole generation of hams who are somewhat dismayed by the adjustments necessary on the older stuff. Don't be put off, the only rule you must follow is to keep the plate current dipped and not let it go high for more than a couple of seconds. Once you do a tune up a couple of times it becomes habit.

go; it can not go back any more because of that cotter-pin you can see in the photo. (the U
shaped tension washer moves back toward cotter pin in use). Is this what ALL R4 shafts look
like, it is "normal" for the skirt to sit that far OFF the face. Is this why they make the
"slanted" skirts for the R4B/C??

It's just resting in an ungrooved shaft.

21051. T-4XB OR R-4B METER REMOVAL

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-18 00:34:29 UTC
From: David Nichols
Topic: 21051 Message: 21051

T-4XB, 101

If you ever get the urge to remove the nuts from the back of the meter on your T-4XB or the R-4B, SLAP YOURSELF SILLY! GO POUND YOUR HEAD AGAINST THE WALL OR A POST, ANYTHING to make that urge go away. DO NOT REMOVE THOSE NUTS!

I admit, I have not read the manual front to back but I have not seen a warning about removing those nuts. If you have a rig with the same meters other than the ones I mentioned. Do not remove those nuts! Let me make myself perfectly CLEAR, DONT TOUCH THOSE NUTS, unsolder the wires.
If you remove those nuts, the meter will need to be disassembled to make repairs. If that fine little meter wire didnt break on me I may still have a working meter when Im done.
It started innocent enough, all I wanted to do was clean it up and repaint the inside reflector. To start out you have to remove the face to get the meter out and then those meter wires are so short you cant take it anywhere. The next thing I knew, a little idea turned into a full day of cleaning what I stepped in.

Thank you Garey for posting the meter pictures. I would have guessed wrong on the placement of the internal lugs. I could not believe those studs where turning on me. Turns out, they dont have a nut holding them in place and they are not fixed in any way.

While Im waiting for the paint to dry in the light reflectors I painted new lines on the knobs. Might as well, I had them off. Its cool and rainy today so paint doesnt dry very fast.

I put the rebuild kit together an successfully installed it in my second AC-4 yesterday. No smoke or sparks, good kit and good instructions, thanks WB8VGE. It really needed the rebuild, I found a couple of cold solder joints and bad caps.

Dont I know how to have fun?

I had somehow been fortunate enough to have removed the nuts on at least half a dozen meters before the first one bit my butt.

That wire's insulation melts if you even give it a sultry glance, so I always cut the wire right at the lug and restrip and re solder it afterwards.

Since one really only needs to do this once every 40 or 50 years, I'm not overly concerned at losing 1/4"
Of wire....

21054. What controls TX efficiency?

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-18 03:43:31 UTC
From: rochep@...
Topic: 21054 Message: 21054

I now know bad finals can reduce transmitter efficiency, but with the SAME finals in two different transmitters I am getting very different power outputs/efficiencies:

The SAME 6JB6 tubes in each TX, each TX set for 70 mA bias, and "aligned" as best I could.

On 10M CW into dummy load:

T4XB: 100 watts output with 0.27 A plate current>>55% efficiency
T4XC: 50 watts output with 0.27 A plate current>>31% efficiency (THIS IS MY MAX OUTPUT ON 10M WITH THE T4XC AND I GET IT IN TUNE, NOT IN CW WITH MAX GAIN)

Since the finals are the same, what else could be contributing to the low efficiency of the T4XC?

paul

Are you sure your meter readings are accurate and reading the actual current? If they are not, you are measuring apples and oranges.

I have found out about the wire insulation too.
Ill never take the nuts off again, they came off all normal and everything. Then I noticed the stud was lose. Oh MY! Oh nooooo!

I got it back together, the reflectors with a fresh coat of white paint inside only. I put new light filters in and some new 755 bulbs. It looks great, the 755's are a little dimmer than the 47's but its better mood lighting. hi hi Really, not quite as harsh as before and the meter still works. I needed some luck.
Now, I bought that set of Sylvania 6JB6 off of ebay. Slightly used, well, good for 65 watts on 28.8. If I push it, I get 115 on 40 meters. My mixed pair was better, I think Ill try some from RF Parts next time. A matched pair of RCA's is about $50.
Now that I have the transmitter back in line I will look it over for an AM carrier mod. Since Im getting about 30 watts carrier at .2 on the amp meter dead key and no gain. Its not squealing or anything just a nice carrier.

So far, I found out that it really did not need to be taken apart, but only until I took it apart.

In the end it was that someone turned the dial too far to the low end and the fork was stuck against the back of the VFO case. Removing the DR-7, and lubricating the now hardened grease on the ball bearings and slowly and carefully reseating the fork got it working.

Since I was there I cleaned everything I could with 95% alcohol and removed as much goo as I could. I then used silicone oil (the only stuff I had, my sewing machine oil seems to have been thrown out, because it was almost empty) to lubricate the ball bearings and the threaded shaft. Since everything was apart anyway, I made sure any lubricant that got on the dials, old grease and dirt were removed.

I did not have a replacement circlip, so I just left it out. I also did not have the correct replacement rubber tube, I had one from a 4 line SPR-4, which is a tiny bit longer, and stuffed it all in there. Since I don't have a set screw for the knob, I used a regular bolt which hangs out the bottom. But it all works, and eventually, I'll get the correct parts.

Geoff.

Paul -

This is just the meter, not counting resistor values, etc. This is WHY I recommend calibrating
at 70 mA :-)

This particular meter, with accurate resistors, reading 270 mA is actually 310 mA.

Remember, <$1 each...!!

Dave -

Yes, 'used' 6JB6s are never a good idea. They test 'strong' (whatever that means) on a tube tester, but remember they're being tested at DC and 60 Hz. You know efficiency falls off starting at the high frequency end ....

Check the resistor values around V11. The current through that tube is what sets the carrier
level. Also R77 to a lesser extent.

Without getting into the accuracy of the front panel
meter I think you are reporting that the maximum power out
on ten meters is low as measured independently of the TX
meter. First of all to copy Garey, make sure your idling
plate current is really 70 ma. If the bias is set correctly
the problem can be low drive. If you have something to
measure the drive voltage at the grids compare the two
transmitters. If you are getting higher maximum output in
TUNE than in CW something is definitely wrong. In TUNE
maximum output is limited by the ALC and is never more than
about 130 Watts although the RX may not make it that high on
10 meters. My T4XB manages around 120 watts on 10.
Lots of things affect efficiency but the type of
amplifier used in the T4 series should make around 60 or 65
percent on the lower bands at least. This is typical for a
Class-AB linear. I don't think your power differences are a
matter of efficiency but something else.

From: Garey Barrell
Topic: 21054 Message: 21064

Paul / Richard -

50 to 55% is typical efficiency for the T-4X(any) transmitters. This is partially due to measuring Cathode current rather than Plate current, but also to other 'compromises' in the matching networks.

Don't forget in CW you need to advance the GAIN control, sometimes considerably, over the SSB/TUNE. As Richard said, the TUNE output is limited by the ALC, and the GAIN 'flattens out'
around 11 o'clock.

This is a good point. The cathode current of course
includes the screen grid current as well as the plate
current. It may not be much higher but enough to make the
efficiency look lower. Maximum efficiency of these
amplifiers is fixed by theoretical considerations. The
theoretical efficiency also does not take into account
losses in the plate and coupling circuits and some tube
losses that increase with frequency.
The operating conditions in transmitters like the T-4 is
a compromise between high efficiency, low distortion,
stability of operation and ease of tuning. The efficiency
could be increased by moving the operating point towards
Class-B but Class-B amplifiers are very fussy about exact
bias and precise tuning. Not worth the trouble for maybe 10%
greater output.

Ok Garey, I checked the resistors.

R56--15K = 16.2
R57--15K = 15.6
R58--22M = 23.2

R77--330K = 347.3

While a couple are high I believe they are yet within tolerance. Do you think I should change any?
I will see if I can get a decent photo of board 4 and send to you. I know these parts arent on it but I am curious about some cap changes there.

Yes, 'used' 6JB6s are never a good idea. They test 'strong' (whatever that means) on a tube tester, but remember they're being tested at DC and 60 Hz. You know efficiency falls off starting at the high frequency end ....

Check the resistor values around V11. The current through that tube is what sets the carrier
level. Also R77 to a lesser extent.

Why won't someone stop me?

Dayton was a wash out. Rained and hailed. Yes! Hailed several times.

It followed me home. Another (!) Drake TR-4.

Serial number 28384

and with some issues. First off....

Garey.....

Why is the dial 25ish kHz off? Not sure of the exact amount but it's off by at least that amount.

when did they (drake) change the front main tuning knob? This one is brushed aluminum instead of the fluted knob.

The audio sounds distorted on strong signals. AGC needs attention.

Other than firing it up, no other tests were made.

And.......

Two Ten Tec Century 21 radios. Both broke
A drake SSR-1 seriously screwed up
Kenwood TR7600. No transmit and missing some display segments

Plus some finals NOS 6JB6s (sylvania) for $22 each. A bunch of 12BA6s and a 12AV6 for the other TR-4. I picked up a few 6HS6s @ $12 each. NOS.

Mike, WB8VGE

Yes, that really should be replaced. They are all the same, except for the Plate supply one.
Not particularly hard to replace, just need a BIG soldering iron. I put aluminum foil over the
wiring on either side of the wall. An iron big enough to solder those radiates enough heat to
curl the insulation on the hook-up wire in the area.

Joe,
In my experience, hands down, the 10-D & 10-DA mic heads, on a G Stand, are far superior to the crystal element D-104, on my B Twins. A well controlled TUG (or TUP)-8/9 stand, will work, but I prefer the non-preamplified, G-Stand.
I have never found a more compatible mic, for my T-4XB. No EV's, Turner/Telex, Heil, or other mic, has had the good reports, from my T-4XB. Although, I'd like to try a Blue Bird, or other commercial, recording, broadcast, or live performance microphone, when I can afford one.
THAT IS, of course, my experience. Others will likely have different results.

Over the years I have used Ten-Tec, Kenwood, Yaesu and transitorized Drake radios. I have a deep voice and the 10-DA works wonderfully for me. My wife has a high voice and she sounds much better with a D-104. I like both because I can switch the heads as needed.

As for an amplifier, it was really intended as an impedance matching device when transceivers switched from high impedance mics to low impedance mics. Unfortunately too many people got the idea that the higher the gain on the amp, the "better" it sounded.

I prefer to bypass the amp completely if not needed, and if it is, start at the lowest setting and work my way up. :-)

Mike,

If the PTO is off on all bands, the same direction and approximately the same amount, it could be a PTO issue. If it is off in "either" direction depending on band, or not off on some bands, then it could be that one or more of the band change crystals could have drifted off. The "dial adjustment" can compensate for such issues to a certain degree. But hey, I'm not an expert on this one.

73,

Evan

If the calibration is off there are a couple of
possibilities: first see where the end points of the dial
are. The dial can be slipped on its hub. If the end points
are off its probably slipped. Another possibility is that
the gears have jumped a tooth or two but I think this would
cause a larger error. The dial can be re-set by reaching
around in back of the dial with your finger and moving it.
Set the pointer at the center of its range when doing this.
A slipped gear is a bit more trouble to fix but not
much. Check the dial first.

richard,

I did a quick check the other night, seemed that the dial stopped in the proper place (the end stops) but will check again.

This PTO has metal gears, but I guess it's possible to have a slipped gear within the clock works

OOOOPs!
I did it again, I was trying to setup the T-4XB with the R-4B and oboy!
I should have paid closer attention to the amp draw I suppose.
I never did hear that bird.
I saw a flash from the final area and a puff of smoke as big as a fist. Oh My!
I turned it over and what do you know? R36, R32, R33 blowed up and stinking like mad, and no Bingo.
I sure hope those Ceramic Composition Resistors work for the 15 ohm 1 watt ones.
I went ahead and ordered some more 2.7 ohm ones for R36 and a few new caps to go with R32 and R33. Might as well replace them while Im playing around in there.
Is there something else that usually goes when this happens?

Maybe next time Ill get to hear that bird tweet. hi hi If I get the parts in this week I could be back in business this weekend.

Yes, that really should be replaced. They are all the same, except for the Plate supply one.
Not particularly hard to replace, just need a BIG soldering iron. I put aluminum foil over the
wiring on either side of the wall. An iron big enough to solder those radiates enough heat to
curl the insulation on the hook-up wire in the area.

Not good..... Do you have a 400 mA or a 500 mA Plate meter???

Sounds like the BIAS supply died..... Hopefully the meter is still good. Was the IDLE current correct???

Boy I dont know Garey, the idle current was fine unless hooking it up to the receiver changes things. It would be a shame for the power supply to die like that after I rebuilt it but it is possible. I was adjusting the cap and listening for that bird. Trying to find the spot, I guess I missed something more important. I double checked my wire hookups so I didnt cross them. Whatever it was didnt take it long to do its work. Just a few seconds of key down and I was done. Ill have to check the meter when I get back out there. I have a realtor coming in today so I have eat and clean up my mess before I cant do anything else.

What exactly were you doing when this happened? Was the
transmitter mode switch in SPOT?
Had you tuned up the transmitter?

No, connecting up the receiver shouldn't make any difference. Even if cables went into the wrong
ports it shouldn't blow up the PA.

What happened is most likely that BIAS voltage on the PA stage was 'lost', or 'shorted', causing
the PA to go from idle current to MAX which kills the Cathode resistors, RFC2, and R36, all of
which are in series to ground.

If you keyed the transmitter without tuning it up first into a dummy load, 'closing the key'
will cause it to draw max current. The TRANSCEIVE ALIGN procedure is done in SSB and SPOT, in
which case the PA is not even enabled, and no 'key' is required.??

When you first go to SPOT, you will hear a 'beat note', kind of a warbling bird sound, which is
the result of a tone modulated at what would be a sub-audible beat. When you adjust C61 you
hear the beat approach and reach ZERO. The Tweet is the 'beat frequency' and just allows it to
be audible all the way to ZERO. When you get down to one or two 'tweets', you can see the
S-Meter follow the tweet strength....

Garey and Richard I believe I figured out the error of my ways.
I started out attempting the transceive alingment outlined in the T-4XB manual. Not finding a signal to play with I then changed over to the instruction set by WB0IQK that I had copied from the internet.

This was my fatal setup, I did not tune up before changing methods. As you know, the manual has you on 80 meters with the preselector at 6.5. I did not change these settings when I switched over to the other method. I wasnt keyed up very long at all and it didnt take long for things to happen. Well thats the way it happened, I did it wrong.

On a better note, I just looked at the damage again. I wanted to check the inductors for continuity. I will have to dig out my meter for a measurement of value. But what I noticed is that R33 is still good, I know I thought it was toast but it did not blow up like R32 did. So I got R32 and R36 and I just got a note from Mouser that my order will ship today. New parts are on the way and I should get them by this weekend.

OK. Yep, classic case!! :-) Check RFC2 for continuity, it looks ok. I've seen the three pi's slammed together from the EMF in a short circuit. it could still have a shorted turn, but
doesn't seem likely.

I see where things went wrong using Mark's procedure......

You must be in SSB. It's been a long time since I figured out what was happening, but seems like it was audio feedback from the speaker to the mic amp via ANTI-VOX that generated the tweets. Closing the 'PTT' in SSB should result in ZERO output unless you speak into the mic.
Closing the 'PTT' in SSB OR CW with the GAIN at CCW results in ZERO output even if you speak
into the mic.

The 'iceberg' in this catastrophe is that "KEY" and "PTT" are NOT the same. KEY in CW with the
GAIN advanced generates a signal and RF Output. PTT in CW or SSB activates the transmitter, but
no signal in CW and no signal in SSB unless you speak into the mic. TUNE activates PTT AND 'whistles' into the mic.

21093. SPR-4 labels

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-21 11:44:48 UTC
From: geoffrey mendelson
Topic: 21093 Message: 21093

I finally sat down with my Brother PT-1000 label maker and an SPR-4 to see if I could make labels that fit.

What I found is that I can make 2 line labels that fit, so you need to make another one for the third line.

You use clear tape with black print. I'll have to look and see if I can get clear tape with blue print, keeping it in the Drake color scheme. :-)

The data should be 2 lines of three characters. So 16.5/8.5/F should be done as one label with 16.5 (return) BLANK 8.5. A second label with BLANK F (return) BLANK is needed.
Something like 7.0/6/E would be done as BLANK 7.0 (return) BLANK (or maybe 2 blanks) 6.......

Settings are:

Size: small
Width: x 1/2
Style: Normal
Margin: Full
Underline: Off
A/F: Off

21094. SPR-4 tuning chart

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-21 15:28:13 UTC
From: geoffrey mendelson
Topic: 21094 Message: 21094

Anyone have an SPR-4 tuning chart?

One that has frequency, preselector, and band letter settings?

TIA,

Geoff.

Thanks, it's a different scan of the same manual everyone has. I think there was only one published, though different versions online have different notes.

It has a chart of what crystal you need for what frequency, but no chart of how to tune the radio. I assume when you bought a crystal from Drake, they included the decal you needed.

My problem is that I have an SPR-4 with lots of crystals added long after the decals were either removed, or left on the radios the crystals came from. Many have faded, and some are penciled in (and wrong).

There probably are enough remaining SPR-4's to crowdsource a decent table.

Thanks and 73,

Geoff.

21103. Loose power cable fried my finals?

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-22 02:41:46 UTC
From: rochep@...
Topic: 21103 Message: 21103

Last night I noticed some "sparking/buzzing" sounds from the back of my T4XB as I was transmitting. Took a peek, it sounded like it was coming from the BACK of the rig; then I noticed my power connector from the AC4 looked like it was coming out, I plugged it back in and the noise went away. (I was messing around back there with KEY and RX ANT connection). I don't remember if I had another transmission after that or not.

Today I went to transmit.. NOTHING. No bias current. Then saw the fuse in my AC4 was blown. Replaced it, rig started up, but STILL no bias current. Hmmm. So replaced the PA tubes with "spares" (I THOUGHT they were bad) but now everything is fine, I transmit fine, bias is fine, >100 watts out on all bands.

Could a loose connection from AC4 to T4XB cause an intermittent that could kill final PA tubes? Any way to make sure the connector is in there TIGHT; mine is pretty loose.

The "good" news; after a new 6EV7 these "bad" Sylvania PA tubes seem great, neutralized nicely and no evidence of oscillation.

Jackson Model 115 - appears to be from the 50's, cathode emission.

It powers up but doesn't seem to indicate when a tube in tested (needle goes all the way to the left). Should be an easy repair or could be cockpit error.

These go for $35-55 plus shipping on Fleabay, send me $20 plus shipping and it's yours. I have a TV-10 and I have no time to mess with it.

In a word---yes
If the bias is lost the PA tubes are gone
Happened to me and that is why I now pay a lot of attention to the condition of the AC-4 power connector and mating pins on the transmitter or transceiver. I clean them thoroughly with contact cleaner and if the connector doesn't feel right, replace it.
Also check the mounting screws for the chassis connector on the transmitter or transceiver by loosening and re tightening the hardware
Drake appears to have connected the ground pin on the plug to the shell of the connector for ground. Should be a wire from the connector soldered to ground to eliminate the mechanical reliability issue. Apologies to all if there is such a connection. I didn't find one in my TR-4, only mechanical.

21109. Re: [DrakeRadio] Loose power cable fried my finals?

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-22 17:45:09 UTC
From: Garey Barrell
Topic: 21103 Message: 21109

Paul -

I'm trying to think of a scenario where this could happen. Yes, the C-J connectors can get 'loose' after _MANY_ matings. I always clean them with DeoxIT and even a pencil eraser when necessary, but only seen a few that would actually come loose, 'on their own'. One problem is
if the PS cable is hanging down behind a table, etc., and put a considerable load on them. So
it's worth taking care that any 'mechanical' load is corrected, on ALL the cables.

Most likely cause of PA tube failure is if the BIAS connection is interrupted as this not only
removes the bias voltage from the PA, it also keys the transmitter! This condition can easily
draw enough current to blow the AC-4 fuse.. Was the fuse correct?? 5 or 6-1/4A Slo-Blo??

The BIAS supply is PIn 9, which is NOT a corner pin, and is on the bottom row, and since it's
the same length as all the other pins it seems strange that it would be the pin to 'break contact' first. I'm thinking it's more likely that the +650V pin, which is on the top, right
'corner' came loose and was causing the 'buzzing' sound. Without the +650, transmitting causes
the PA Screens to 'become' the Plate, and with little to no dissipation capability, probably
vaporizing them, leaving tubes with NO Screen. Since a Pentode without Screen voltage will NOT
conduct, no idle current (or any other current!,) is possible.

So... Lesson is, make sure the connectors are firmly engaged, with the cables arranged so that
they are not 'hanging' from the connector. Also power off before pulling a radio out from under
a shelf, etc., that could put a strain on those connectors.

Topic: 21103 Message: 21110

Yes, I have been fiddling so much with the radio, taking it from my shelf to my bench (for neutralizing finals, testing different tubes, alignment, etc...) that I think the power cord was not seated in there right, sort of "dangling". I have learned my lesson (the expensive way). My 6GJ5 "replacements" are on the way.

paul

Greetings all, I am looking to purchase a pristine b line. One that is in perfect working order with all the cables. Also an ac4 with the upgrade , and an ms4 speaker. I will consider a b line that has an issue or two as long as it is pristine cosmetically. If anyone knows of one please let me know. Thanks. W6dst. "73".

Brian,

Welcome to the world of L4B amplifiers. As to restorations, it's not possible to address restorations unless it is known what needs to be restored. As to upgrades, two of the ones I usually do are the power supply (Heathkit Shop or Harbach Electronics retrofit boards), installing an RCA female connector for the PTT line, and a "soft key" for the PTT (e.g. Ham Gadgets UKA-2) so that it can be used with newer solid state rigs as well as vintage rigs.

In terms of other things to look for/at, please see a posting from earlier today regarding the VIMEO and YouTube videos from the Drake Forum from Hamvention 2014 last weekend. Things to check before you power up are addressed.

I'm sure the Drake experts will be able to guide you through whatever assistance you might need.

73,

Evan, K9SQG

Garey

Found the issue.

The R70 (zero pot) was open. This caused all the metering current in the bridge to flow through the s-meter.

As it turned out, the previous owner had replaced the s-meter with a 20 ohm unit (heavy shunt type) thinking the full scale meter issue would be resolved this way. Some minor scratching on the case near the zero pot adjustment is evidence he had an issue with the zero pot, as was some sloppy resolder work.

Anyway.....I replaced with a new 200 ohm pot and reinstalled the standard issue 230 ohm s-meter.

Now the meter zeros nicely and the s-meter deflects as it should.

p.s. this is the second time I've had a bad R70 in a TR4-C.....tough to find one that fits ! Usually the thread is 3/8" dia. on ones you find - the TR4-C needs a 1/4" thread mount.

Thanks for helping me resolved this.

Bill -

Cool! Always nice to get one going again......

Always tough to figure out what's happening when you have 'two' failures, bad meter & open pot!! Good catch!

Yes, R70 often fails as a result of C135 shorting, causing the 6AQ5 to draw way too much current. If the guy is lucky, he figures out that C135 is shorted, replaces the cap before the
Output transformer opens, and puts in a new tube. Got audio, now the S-Meter doesn't work!! Why would the AF OUTPUT tube affect the S-Meter?? :-) Time to sell the radio.............

Glad you got it going.

21118. RV-4C

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-23 02:16:41 UTC
From: David Nichols
Topic: 21118 Message: 21118

Hello Everyone,
Well I have a question on the VFO operation.
I just got this in today and have cleaned it and painted the scratched up case.
Its looking a lot better but when I turn the big knob it slips. hi hi
Im just spinning my knob and the dials arent turning very much.

It doesnt happen all the time but to much for me to be happy with it.
The gears have popped out at least 4 times on me and I dont see any instructions in the manual about lining the dails up properly. I figured the spring loaded release mechanisms out and lined up my zero's.
But it still slips, so now Im thinking the rubber clutch is working to hard. It seemed pliable but I didnt remove it yet. It might have some grease or something on it so Ill do that now.
Any suggestions?
David - KX7C

David -

Does the frequency change normally as you tune?

If it IS, the 'clutch' is slipping. You need to press in on the knob as you tighten the setscrew.

Well I pulled the rubber clutch. It isnt as pliable as it seemed, I can make a mark in it with my fingernail but I have tough fingernails. The thing slips more now than it did before I cleaned it. Pushing the VFO knob into it doesnt seem to help either.
Looks like its time for a new clutch.

I dont know Garey, Im still working on it. Im not close to hooking it up to the TR-4CW yet. I had a couple of rust spots on the deck to deal with and I have the face back on it now. I think I will see if I can rough up the ends of the clutch a little and see if a piece of paper inside it will make it work till I get the new clutch in.

Im working on 4 Drake pieces now.

Question on the TR4CW, do you think I should realign it since I installed the new 40 meter xtal?
The old one was off about 165 kc's.

Thanks for the great reply! The L-4B came with all the Harbach mods still in their plastic bags. The problems I am having are that someone removed the two large resistors that mount on each side of the power supply transformer and had placed a large string of diodes in line with the high voltage line to the board. I took all that out and installed the Harbach board I have to get the resistors and finish that up.

I then took a look at the RF deck and someone had done some home brew soft start mod and also installed a modern antenna relay. They had cut and moved a lot of wiring and removed the safety interlock so I have spent the last couple days trying to sort that all out and get it back as close to stock as possible before I install the Harbach soft start and soft key. Luckily my brother has two working L-4B's and I have one here to compare which has been a big help so far. I am having trouble finding an original style relay and the interlock system. I have been searching with no luck. Harbach did carry the relay but he is out of stock and told me he didn't know when he would get more in because he has to source a new supplier. So really I have kind off hit a brick wall until I find the parts I suppose.

From: geoffrey mendelson
Topic: 20472 Message: 21123

I have an RV-75 that I got with a TR-5. If I want to put it on a TR7, the instructions say I need a cable which goes on the accessory plug (not the one that powers the RV7) to adjust the RIT. Is this needed for general operation? Can I use the RV-75 without it?

The other question is more philosophical. I have an SPR-4 which receives well on LF and MW broadcasts. I plan to hook it up to a PA0RDT type mini whip amplified antenna, so that it can receive something here besides noise. I understand the TR7 can be modified to receive on LF and MW. The easiest way was to use an AUX-7, which I had 20 years ago, but that went with the TR-7 I traded when I left the US. Is it possible to still get AUX-7s? I seen have articles about a home made replacement for it, is it possible to get them assembled, or at least a kit of ALL parts?

The PA0RDT antenna has been an experience in how many different vendors one can buy from on eBay, (and off it) at the same time. Looking back on it, I should have bought a kit, or an assembled version, or even the much more expensive, and more robust MFJ equivalent.

I doubt that any other mod could be done by me. I am still searching for someone in Israel who works on TR-7s, but I am afraid that by default, I am the one. :-(

Is it worth it? Besides the nice digital display, is the TR7 a better receiver than the SPR-4? My TR7 has a 500 and 300 Hz CW filter, but the 500 is not working and if it turns out to be defective it will be replaced with a "poor man's AM filter". Right now I listen to AM broadcasts on SW bands using the passband tuning trick.

Thanks and 73,

Geoff.

Garey to answer you question, no it does not change the frequency. Infact, it seems to be dead.
The red lights work and indicate that circuit is up. My new dial light is not working. There is no output when I use the VFO to xmit and the receive noise is not right. So I will say it does not work with my TR-4CW.
I should have bench tested this sucker before I put it all together. Now I have to take it apart and bench test it anyway. The sad thing is, the guy I got it from swore up and down it all works. That he was using it and it worked fine. No, I didnt get it on ebay.

Good Morning Garey,
Well its 2320L for me and Im sure you are snoring by now. hi hi

I got it to work, I was not getting my 12 volts to the tube and the dial light.

I cleaned the power plug prongs again and worked the plug into the socket a few times.

Its all working now and changing frequency as I think it should. I had to adjust the dial a little, about 10 kc's and it seems good now. I am able to receive and transmit with the VFO and that was the desire. hi hi
I pulled the VFO knob off of the TR-4 since I had it on the bench and boy what a difference between the rubber. The TR-4 has a soft black one that is springy. The RV-4C has a hard grey one, I dare say it is original. But it is very hard compared to the other one.
Im done for the night.

I know many people love these little E-Field Probe whips.
I spent many years and accomplished a few "first" in Lowfering.
The E-Field Probe would be my very last choice, especially in
a high-noise environment. If one is serious about Longwave,
a tunable loop- even the small desktop ferrite-rod type-
is far and away a better choice. Heard many of the 600 Meter
stations reliably with one not much bigger than my hand.
Try one and you'll use the E-Field Probe for a back scratcher.
If you have a quite location and lots of open space,
a very long wire laying on the ground (beverage)
will make you want to throw rocks at any smaller antenna.

Regards,
David S.

Thanks,

My problem is where I am. I am in an apartment building, on the side of a mountain. The mountain blocks all signals to the south and many to the west. There is a lot of noise from everything electrical and electronic here. All I can do is put something that no one recognizes as an antenna.

Things are so bad that a GE Superradio 3 can only receive one or two stations inside my apartment. Then only if I sit at the north window.

Many of my neighbors would force me to take down anything they recognize because if it is an antenna, it must be putting out dangerous radiation.

The PA0RDT design, over the MFJ for example, only looks like an antenna if you build it in the pipe type case. If you put it in a lamp or a flowerpot, no one will notice it. :-)

So I am stuck with what I have.

I do have a lot of varied length ferrite rods, I bought them a few years ago to experiment. They were made in the Soviet Union, so they have been around for a long time. I got them really cheap, someone I noticed sold them on eBay with crystal radio instructions for $10 each. Ouch. If you have any designs please let me know, I'd like to try them.

I did find a way of cutting the cost of the electronic components to less than half, by substituting a 2n3866 instead of a 2n5109 transistor.

Geoff.

David -

OK. I guess it depends on how you did the alignment before. If you set it to the correct 'frequency' to peak the alignment, or if you just set the 'dial' to the marked frequency. If
the latter, it wouldn't hurt to go through and tweak up the 40M band on the 'correct' frequencies. Actually it won't hurt either way!

But you don't need to do anything other than related to 40M, no BAL MOD, etc. Just Mixer and RF
adjustments.

H-Field antennas like the Ferrite loops seem to me
to be much less bothered by local terrain.
And the ability to "steer" them to cancel noise will
pull many signals out that are completely buried
in the noise from an E-Field Probe.

About a third of the way down this page:

http://theradioboard.com/rb/viewtopic.php?f=10&t=5260&start=15

is a diagram for the Palomar LA-1 ferrite loop antenna.
It's a simple device but it works very well.
I don't recommend buying one- they command a hefty price.
You should be able to build one just as good in an evening.
Wind a center-tapped coil on one of your ferrites.
You'll note a big increase in signals when it's tuned to freq.
You can cut thin wood or Plexiglass and copy the LA-1's
friction-fit coil mounting scheme so you can steer and tilt it,
or devise your own.
Google "Palomar LA-1 antenna" for more info.

Mike -

Probably the Heathkit HO-10. The Collins guys like the SB-610 because it has the rounded cabinet corners like the S-line.

The HO-10 is older, and many have had transformer failure, but if you can find a good one, AND
replace the HV PS filter caps that are the usual reason for transformer failure, and a few resistors that have drifted it makes a nice scope. I've seen at least one 'Drake' HO-10, but
can't find the photo. I've also seen a SB-630 put into an MS-4 cabinet, it might fit into a TC-2/6 cabinet, but doubt you could find one.

Brian,

When you replace the resistors in the power supply, you might consider replacing the 5 K 7 watt ALC resistor on the underside with a 20 watt equivalent. When I rebuild the supplies, I use either a 20 watt variant or two 10 K 10 watt resistors in parallel. Otherwise, failure of the original resistor resistor results in failure of the ALC pot on the RF deck; while I have spares, they are difficult to source.

Not sure what kind of soft start was installed but there are two considerations here--soft start for the filament transformer and tube filaments, and soft start for the capacitors in the HV supply that are fed from the HV transformer. For me, soft-start for the filaments is the more important and thus I have installed thermistors in the primary circuit. As to the HV, I've never had a HV failure due to an inrush surge over decades of operating Drake linears; too, a Drake engineer told me that the DC resistance of the HV transformer secondary limits the surge current due to the capacitors. As a side note, I use an external switch (Ameritron ICP-240 which is NOT a soft-start circuit in spite of what the advertising states) to ease the burden on the L4B power switch although rebuilding the switch can be done quite easily.

The interlock sometimes becomes available on Ebay and, since it is not an overly complex device, one can be fabricated in a home shop. The changeover relay can sometimes be found (used) on the Ebay auction site or elsewhere. Putting out a request for such a part on the free Internet sites (e.g. QTH, QRZ, eHam, etc.), and the HF swap nets, will often result in responses for what you need.

I hope everybody has a safe, enjoyable Memorial holiday weekend. Hopefully it will bring physical, if not financial, recovery from last weekend's Hamvention. But let's not forget the true meaning of Memorial Day.

73,

Evan, K9SQG

Subject: [DrakeRadio] Re: Hi all

Thanks for the great reply! The L-4B came with all the Harbach mods still in their plastic bags. The problems I am having are that someone removed the two large resistors that mount on each side of the power supply transformer and had placed a large string of diodes in line with the high voltage line to the board. I took all that out and installed the Harbach board I have to get the resistors and finish that up.

I then took a look at the RF deck and someone had done some home brew soft start mod and also installed a modern antenna relay. They had cut and moved a lot of wiring and removed the safety interlock so I have spent the last couple days trying to sort that all out and get it back as close to stock as possible before I install the Harbach soft start and soft key. Luckily my brother has two working L-4B's and I have one here to compare which has been a big help so far. I am having trouble finding an original style relay and the interlock system. I have been searching with no luck. Harbach did carry the relay but he is out of stock and told me he didn't know when he would get more in because he has to source a new supplier. So really I have kind off hit a brick wall until I find the parts I suppose.

Dave, thanks.

I looked at it and it would probably fit my needs. I have everything except the capacitor.

I have three questions. I could not find by a quick web search:

1. How many turns of what wire does one need to put on the loop?
>
2. It looks like the coils are shorter than half of the rod, and wound at each end, instead of one coil either spread out along the length, or in the center.

3. I have more than twice as many J310's as MPF102, would they work?

TIA,

Here are a couple of thoughts after looking at the schematic:

The transistors appear to be drawn from the TOP view. This would place the Gate on the left side, connected to the coil, where it belongs.

I don't feel the connection shown between the transistor's center pin (Source) and the junction between the two 4.7k resistors is correct. It would elevate the sources of both FETs to +9v and bias them OFF. I would eliminate it.

> 1. How many turns of what wire does one need to put on the loop?

That depends on a number of things, such as the permeability of the ferrite, the frequency of interest, etc. The bottom line is you need enough inductance to establish resonance at your frequency of interest with the range of capacitance values provided by the tuning cap.

> 2. It looks like the coils are shorter than half of the rod,
> and wound at each end, instead of one coil either spread out
> along the length, or in the center.

Ferrite rods work best in these applications when the length of the coil is made small with respect to the total length of the rod.

> 3. I have more than twice as many J310's as MPF102, would they work?

MPF102 have become obsolete. J310s are much better devices. You may need to decrease the value of the 1k resistor shown the schematic, as 1K may be too high for the J310s.

Finally, you don't need to use a ferrite loaded coil to build an effective H-Field probe antenna for use on LF frequencies. I typically use air-core coils wound from multi-conductor ribbon cable. These coils are typically several feet in diameter, and are hung from some kind of non-metallic support structure. I have found no need to electrostatically shield these coils, because I typically terminate them in high-Z balanced, differential amplifiers, similar to the Palomar unit referenced above.

And on much lower frequencies (60 kHz and below), I use an instrumentation amplifier, like an Analog Devices AD620, to buffer and amplify the output of the coil.

I had a look at the schematic. All the paths to ground
from the pin go through diodes except a lead to the PTT
terminal on the mic connector. . Try reversing the leads to
the ohm meter and see what difference it makes. The
handbook does not have specifications for the meter.

Garey:

Yes, I get about -5 in receive and < 1 in transmit so I will assume this portion of the circuit is working correctly. I had loaned out my TR4 to a ham that does plenty of CW work and he had it for a few years, all working good until recently where the K1 relay chatters with the key installed.

So I brought the rig home and started troubleshooting. When I tune up the rig (X-CW) either it will load up correctly or simply not load up and I can still hear audio. When I use a Mic, PTT will close K1 and speaking into the Mic I can see modulation peaks.

I cleaned the K1 relay contacts and function switches, no improvement. The PS was updated a few years back with the Heath board and all voltages look good. Adjusting the Vox, Anti-Vox did not seem to improve. I swapped out V19, V18, V17, V16 and V2 all with no improvement. The bias was measured at -60 with a DMM.

However when I tap the chassis in the area near V2 (in the X-CW position) the the sidetone sometimes comes through the speaker and occasionally K1 kicks in so I am now looking into that area to see if that area is the source of the problem.

Thanks,
Bruno KC2ESI

AUX-7s show up now and then on eBay, but they command a premium price. The most cost effective way to find one is in a radio. There are no kits that I know of. I started work on a replacement board, but the learning curve on the CAD software I have is pretty steep and I haven't had a lot of time to persue it. It's easy to "fake" an AUX-7 for LF with a few diodes on the bottom of the parent board:

http://www.zerobeat.net/drakelist/drakemod/tr7mod.html

The foil cut is to enable all-band transmit. This mod is a cheat, and there's a better way that involves a little bit more work.

Topic: 21139 Message: 21146

Typical Voltage and Resistance charts of the time were made with an 11M input impedance Vacuum
Tube VoltMeter, quite often one of the many models from Heath. The MAINTENANCE section of the
manual also specifies an 11M VTVM, and in fact later manuals usually specified such with the V &
R tables, along with specific front panel switch positions on the radio, all of which 'can' affect these readings.

As Richard noted, many of these resistance paths go through diodes on their way to chassis ground, which is the reference point for these readings. ANY resistance reading that goes to a
power supply bus goes through a diode before it gets to ground! So polarity of the DC voltage
applied from the ohmmeter will affect the resistance readings considerably in some instances.
VTVMs almost all used a similar circuit and polarity was 'specified' because the (-) lead was an
alligator clip and the Probe was touched to the specified point. There is also variation depending upon the magnitude of the voltage applied by the meter, which was 1.5 VDC is most all
VTVMs of the day, with some analog Volt OhmMeters having up to 30 VDC for even higher ranges.
Most DMMs use very low voltages, and while color coded, the typically leads are BOTH probes,
which the tech tends to use interchangeably! The internal polarity of the ohmmeter voltage is
also not consistent, probably because most meters are 'auto-polarity' so nobody bothers.....

So. Unless you have a Heath, (or EICO, or RCA, or Precision, or Knight, or Conar, or ....,)
VTVM, I would put the value of resistance measurements in troubleshooting near zero. Even the
voltage table readings are suspect, especially the Grid readings, specifically oscillator stage
Grids. Throw in the occasional table entry from an earlier model not being changed when the circuit changes, and it's hardly worth the energy! There is one entry on a table where the resistance of a tube pin to ground is listed as 'infinite', and there is a 10k resistor to ground. Another is the Screen voltage on the audio output tube is 200 volts and the table shows
150 because earlier models used the regulated voltage.

So start with the Voltage readings. If any are more than 20% off, look at the schematic and trace the path to the voltage bus. If there are resistors, measure the voltage on either side
and use Ohm's law to see if they 'make sense'.

The problem is that V2 is operated as a phase shift oscillator in CW, generating the SIDETONE
and keying the relay. This is usually V2, a less than reliable tube. If you're confident of your replacement then you'll have to look at the wiring around that tube, especially R126 - R130
and the associated capacitors, which is the phase shift network. Do the screwdriver test first,
check every screw in the area to make sure it is tight. Examine solder connections to be sure
none are cracked or shorting.

You're in the right area, just figure out why that 'oscillator', ISN'T and you'll have it! Possibly still a tube, or 'mechanical'.

Hi

In some models of TR4c the relay controlled by the valve 6ev7 was replaced with a normal relay to 48 volts and with another type of valve, who can give me news about this change, thanks

Jim, thanks.

I was looking at the set of extender boards I bought for the TR-7 and
IMHO, there is not a lot more technology in the AUX-7. It may need more
work to get them designed, and more soldering to populate them, but one
of the extenders is fairly complex.

What I would need, and I think would be popular (as popular as an add on
for an almost 40 year old radio would be), would one that slides in
(hopefully only one way), and gives you the three low bands reception,
and WARC band transmission. I understand that the all frequencies
transmit mod is cleaner to use, but this keeps it as close to stock as
possible.

Is the guy that sells the extender boards on this list?

Frank -

Late models of the TR-4C substituted a 6FQ7 when Drake was unable to get production quantities
of 6EV7 tubes.

The circuit is functionally equivalent, and the tubes are interchangeable. Where used, the original Varley relay with a 15k ohm coil, replacing it with the new P&B Tyco R10-E1-Y4-V2.5k
(48 VDC) relay requires the installation of a 1.5k, 1W resistor in series with the coil. R143
should also be checked, older versions had a 680k resistor, the 6FQ7 needs a 330k at R143. The
6FQ7 is unfortunately a choice of the audiophile crowd, so is usually considerably more expensive than the 6EV7. [Either tube will work with either relay]

That was a lot of fun. I did more research and found out a lot I did not
know. The LA-1 is the box, not the loop. The loops are separate. They
plug into a stereo type plug (1/4 inch?) on the top, hence the T(tip), S
(sleeve), R (ring) on the drawing.

I found that Universal Radio had the specs for the loops on their web
page for the LA-1, and using a resonant frequency calculator could
figure out the inductance needed. I have a Chinese inductance meter, one
of the little ones with no manual, but I guess I can get it to do what I
needed when I wind the loops.

Using the spec of a capacitor that goes from 25-875 PF (wow!!!), I took the lower frequency, reduced it by 10% and figured out what the inductance should be, when I calculated the high end using the inductance I calculated and the lowest value of the capacitor, I found that it had a lot more range than listed.

The loops are: (official frequency range)
OMEGA: (10-40kHz) 376mh.
WWVB: (40-150kHz) 27mh.
BCB: (550-1600kHz) 120 uh.
160m/80m: (1700-6000kHz) 12 uh.
HF-1: (5000-16000Hz) 1.47uh
mh are milihenrys, uh are microhenrys.

The 160/80 and HF-1 loops are wire loops with no ferrite in them. They came in plastic tubing made into a square, with only azimuth adjustment. The other loops are wound on ferrite rods, and have both elevation and azimuth adjustments.

For my purposes, I figured that I could just build the loops I wanted, without the elevation feature. Since I don't have a variable capacitor (but all the other parts including the ferrite rods), I could just get a cheap 15-365PF capacitor similar to the ones used in crystal radios. Since Universal Radio sold an LA-1 with HF loop for under $100 in Februrary, it seemed foolish to me to duplicate it if the parts cost close to that price.

With a 365PF capacitor, I found I could use: The second frequency is the top calculated resonance with a 15PF capacitor. I doubt it would really go that high, and with the HF loop have any gain.

LF: 3.08mh. 750kHz.
BCB: 2.83 uh. 2400kHz
160/180: 29uh. 7600kHz
HF: 3uh. 23mHz.

>

Not much chance of my ever seeing one of those, or even if I had one
receiving anything on the lower frequencies. From other's experience I
am well outside the range of both WWVB and the 50kHz EU stations.

And to keep it the least little bit on topic, am I correct in assuming
that if I were to build a single, not split loop to those specs, and
plugged it into the loop socket of the SPR-4, it would work?

Thanks and 73.

Geoff.

From: David Nichols
Topic: 21152 Message: 21152

Hi Garey,
I have confirmed the fact that my T-4XB did not have the negative voltage to the finals when the resistors blew.
I have replaced the resistors and repaired the problem with the bias voltage. I have attempted to tune up and I dont like what it is doing. I believe something else must be awry. When I get it to max power the Plate tune is at 3 o'clock and it should not be. I feel some capacitance must now be missing. What are the chances on C61 being bad? I will check but I thought you might get me to the spot I need to look. Those road maps called schematics confuse me sometimes. Is there another tube that might have bit the dust? The good thing is I didnt get anymore fireworks when I turned it on.

The AUX-7, if you ignore the fixed frequency (crystal) oscillator stuff that most people will never ever use, is just diodes and wires. It doesn't get much simpler than that.

>What I would need, and I think would be popular (as popular as an add on

The board I started work on would have the flexibility to do that. Offering it as a "kit" is not something that is in the cards right now as logistically I just don't have the time for it.

>Is the guy that sells the extender boards on this list?

I don't know, but his info is here:

http://www.wb4hfn.com/Services/W7AVK/tr7ext2.htm

... which evolved from my original extender board page here:

Ok Garey,
I got things mixed up on the upside down rig. I thought I was on 40m and I had the switch on 80m.
I was looking for it to tune up on 40 and things was not looking right. Now that I have that figured out it looks a lot better. Thank goodness! I think I have messed it up enough already.

That said, I did install a pair of 6JB6's, ok tubes. Not new but fairly well matched and good.
I replaced the blown resistors R32/33 with a matched pair of Ohmite Ceramic Comp. 15 ohm @ 10% 1watt. I got six so I could pick the closest ones to use.

I replaced R36 with KOA Speer Metal Oxide 3.3 ohm 1/2 watt @ 5%.

1. Both finals are light up and I now have about 80 watts output on 7.2 MHz. I double checked.

2. Idle current is setup and looking good. The voltage across the resistors is different. R33 on V6 measures about .5+ the digital meter is fluctuating and did not settle down. R32 on V5 is lower at .4.
3. Dummy load is good its the dummy running it I wonder about. hi hi
4. Load looks better now, on 40 meters @ 3.5 and the Plate is @ 7.
5 Plate meter is reading .22.
Moral of the story, Make sure you are tuning up on 40 meters with the switches instead of your mind.
I think I keep thinking its an 80 to 10 meter rig and I disregard the fact this one has 160 in it.

I hope you have a good weekend Garey

OK, we were all where you are once upon a time! :-)

Your 6JB6s aren't too well matched. The 'fluctuating' reading on R33 is not good, and probably
indicates a flaky tube. If your 6JB6 tubes were 'matched', you would read 0.525 VDC across
either 'perfect' 15 ohm resistor and the meter would read 70 mA of IDLE current. Right now, V6
is passing 33 mA of idle current, and V5 is only passing 27 mA for a total of 60 mA. You need
to select a new R38 value that will make the meter read 60 mA, then re-adjust the BIAS for 70
mA. Since the tubes aren't matched, one is handling 21.6W and the other is 17.6W for a total of
39.2W than the 45.5W, equally shared that it should be. This is not all that important right
now, but should be fixed if you want it RIGHT! :-)

I replace R36 with a 1W resistor, but that ceramic comp will run red hot without changing value,
so not really all that important.

Your 220 mA is 144W input, which should give you about 79W output, right where I'd expect.
That's good, although low. Perfect would be .340 on the PLATE meter, for 220W input, and about
122W output. You could load for more, but those are the design values.

A new pair of PA tubes, and a new R38 and you should be right on the mark!! Good work!

Ill read this again to make sure I follow what you are saying.
I was just able to neutralize the tubes so I will check the readings again.
I am pretty happy with the adjustments now, they look ok to me. I will take another look with the volt meter now and see if it changed anything. Ill get back to you on what I find.

David -

OK, we were all where you are once upon a time! :-)

Your 6JB6s aren't too well matched. The 'fluctuating' reading on R33 is not good, and probably
indicates a flaky tube. If your 6JB6 tubes were 'matched', you would read 0.525 VDC across either 'perfect' 15 ohm resistor and the meter would read 70 mA of IDLE current. Right now, V6
is passing 33 mA of idle current, and V5 is only passing 27 mA for a total of 60 mA. You need
to select a new R38 value that will make the meter read 60 mA, then re-adjust the BIAS for 70
mA. Since the tubes aren't matched, one is handling 21.6W and the other is 17.6W for a total of
39.2W than the 45.5W, equally shared that it should be. This is not all that important right

21160. Re: [DrakeRadio] T-4XB BIAS SUPPLY

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-24 23:45:29 UTC
From: David Nichols
Topic: 21152 Message: 21160

Alright Garey,
I went to change the tubes because there wasnt any difference. The suppressor came off in my hand so I am making some new ones. I have another fresh set of Sylvanias on the way and am hoping they are as good as advertised. I do have another set I can use for now. When I get it back together I will get on with what I was doing. I am using some ceramic comps to put the coil on they are smaller in diameter but equal in length so there will be a little gap between the resistor and the coil. Ive seen some of them be just loops so Im thinking this wont matter.

Heh...I saw that on eBay!

I sent a 'private' to him, questioning the price of shipping...and he also selling an MS_4...also ridiculous shipping...What was it...60 for the PS and 40 for the box....GAH! I won't bother to bid on either.

The MS-4 fits in a Regional Rate C box just fine...not much spare room, but we are only talking 5 pounds tops...he won't do it....BTW..shipping on that 'C' box from Merrick (I think that is where he is) NY to my home in Reno, Nevada, was only 19 bucks.

I think Paul K. has an AC-3 that I will buy from him...I need it so I can sell an Early Drake '4' set....T-4x and R-4A. Besides...I trust Paul! The guy on eBay..don't know him from Adam.....

Greetings Bill, wb9cac, I am ready to purchase your b line as long as the face plates are not scratched and the lettering and finish is not worn or faded. I'm not too concerned about the ms4 appearance, that can be refinished. Are there any known issues past or present. Just to recap, b line with cables, ac4 with upgrade, ms4, & a d104 mic for $450.00 plus shipping. Sounds good to me. Still would like to see a few pics. Let me know when you can.
Thanks Bill, Dave. W6dst. "73",

21166. Re: [DrakeRadio] TR4 resistance chart measurement V19 pin 2

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-25 02:10:09 UTC
From: ralph.gent@...
Topic: 21139 Message: 21166

Garey:

Agreed, the V2 area is the one of interest. I did a double take and this time around measured the voltages at the pins. Both pins 1 & 2 showed about 200VDC (definitely no good) and when tapping the chassis the voltages would disappear. As I look at the schematic the only way the grids would get that kind of voltage is via the V2 plate. So I installed another 12AV6 (third one) and this time around all seems to be working correctly; initially that is.

Tuning up in X-CW is right on; however, when the relay returns back to RX the audio almost sounds as if sideband was changed even though lower sideband is lit on 40. Engaging X-CW a few times and sometimes the audio sounds correct and off sideband the next time around; I get the same effect switching the sideband function. I don't have another 12AV6 so I'll send away for a few and hopefully they will turn out good.

Thanks for your help, I'll report back when I get another 12AV6.

Thanks,
Bruno KC2ESI

Bruno -

OK. That 12AV6 isn't one of my favorite tubes... ! :-)

The Carrier Oscillator is shifted off frequency in CW by the small relay on the back wall right
near the CAR OSC. Sounds like perhaps it isn't operating reliably. It's an interesting circuit, the relay coil (12 VDC) is in series with the +150 VDC to the screen of V15. The relay
is de-energized on SSB by shorting out the coil with switch contacts on the back side of the
first wafer of the MODE switch. The switch is 'closed' (shorting out the relay coil) in CAL and
SSB positions, and 'open' (causing the relay to close) and shift the CAR OSC about 1 kHz up,
ONLY when the T-R relay is closed. Confusing, I know... Essentially the relay K2 (CAR OSC) is
energized ONLY when CW or AM MODE is selected, AND relay K1 (T-R) relay is closed. When the transmitter VOX releases, BOTH relays should de-energize.

> Agreed, the V2 area is the one of interest. I did a double take and this time around measured the voltages at the pins. Both pins 1 & 2 showed about 200VDC (definitely no good) and when tapping the chassis the voltages would disappear. As I look at the schematic the only way the grids would get that kind of voltage is via the V2 plate. So I installed another 12AV6 (third one) and this time around all seems to be working correctly; initially that is.
>
> Tuning up in X-CW is right on; however, when the relay returns back to RX the audio almost sounds as if sideband was changed even though lower sideband is lit on 40. Engaging X-CW a few times and sometimes the audio sounds correct and off sideband the next time around; I get the same effect switching the sideband function. I don't have another 12AV6 so I'll send away for a few and hopefully they will turn out good.

Hi Garey,

Very interesting.

I just checked my TR-4C S/N 36805. V19 is a 6EV7 and the circuit diagram I'm using from your CD is called "TR-4C Schematic 35161" which shows 6EV7. This is the correct circuit to be looking at, Yes?

However my installed relay is a 48vdc with 2.5k ohm coil. Early on when I had trouble with relays pulling-in I bought a spare. It is also a newer 48v 2.5k ohm coil. Since the new relay did not "fix" the problem at the time I back swapped to the original unit that was installed.

However I've just checked and I do NOT have a 1.5k ohm 1 watt resistor in series with the coil as shown in the later circuit called "TR-4C Schematic 42500". This circuit gives this resistor designation R194. (Which just by the way, is missing from the version of your TR-4C service guide I have. But paradoxically, the same guide lists R143 as the newer 330K and not the older 680K. Anyway no biggie but I thought I'd mention it in passing).

So assuming I have correctly got my head around all this. My questions are:

What effect/symptom is caused by running the rig with the 2.5k coil with R194 missing? As it begins to look like the previous owner replaced the original relay but didn't know to install R194.

Next question. Where did Drake install R194. At the base of V19 or behind the the relay on the relay PCB?

From: David Nichols
Topic: 21152 Message: 21169

Ok now, Garey, I changed the tubes out but when I couldnt neutralize them I changed those out.
Now I cant find a sweet spot to neutralize these either. The voltage on the resistors looks good with these but its like the neutralizing cap isnt doing anything.

Am I going to have to change the suppressor resistors back to carbon?
I have a pair so I can do that, it was working before I changed those.
Ill see tomorrow, Im getting tired out tonight.

Subject: Re: [DrakeRadio] T-4XB BIAS SUPPLY

Alright Garey,
I went to change the tubes because there wasnt any difference. The suppressor came off in my hand so I am making some new ones. I have another fresh set of Sylvanias on the way and am hoping they are as good as advertised. I do have another set I can use for now. When I get it back together I will get on with what I was doing. I am using some ceramic comps to put the coil on they are smaller in diameter but equal in length so there will be a little gap between the resistor and the coil. Ive seen some of them be just loops so Im thinking this wont matter.

Ill read this again to make sure I follow what you are saying.
I was just able to neutralize the tubes so I will check the readings again.
I am pretty happy with the adjustments now, they look ok to me. I will take another look with the volt meter now and see if it changed anything. Ill get back to you on what I find.

David -

OK, we were all where you are once upon a time! :-)

Your 6JB6s aren't too well matched. The 'fluctuating' reading on R33 is not good, and probably
indicates a flaky tube. If your 6JB6 tubes were 'matched', you would read 0.525 VDC across
either 'perfect' 15 ohm resistor and the meter would read 70 mA of IDLE current. Right now, V6
is passing 33 mA of idle current, and V5 is only passing 27 mA for a total of 60 mA. You need
to select a new R38 value that will make the meter read 60 mA, then re-adjust the BIAS for 70
mA. Since the tubes aren't matched, one is handling 21.6W and the other is 17.6W for a total of
39.2W than the 45.5W, equally shared that it should be. This is not all that important right
now, but should be fixed if you want it RIGHT! :-)

I replace R36 with a 1W resistor, but that ceramic comp will run red hot without changing value,
so not really all that important.

Your 220 mA is 144W input, which should give you about 79W output, right where I'd expect.
That's good, although low. Perfect would be .340 on the PLATE meter, for 220W input, and about
122W output. You could load for more, but those are the design values.

A new pair of PA tubes, and a new R38 and you should be right on the mark!! Good work!

I am in need of the long springs mounted on a C-line PTO for my T-4XC transmitter I recently acquired and am restoring. (Puts rear tension on the PTO shaft.) I've never needed one before, but it seems to me this was once covered as a topic and there was a source given. By chance was it maybe McMaster-Carr or maybe Small Parts? So head me in the right direction. Where can I obtain one?
Thanks,

Lee, w0vt

Does anyone want a pair of the L4-B power supply boards? As a preventative effort I have replaced the originals with a Harbach kit. The original boards are complete except the one from which I removed the brackets to install the harbach board.

It was twenty years since I fired up the L4-B so, as the saying goes, “I worked fine the last time that I used it!”

Contact me off the net if you can use them,

This is not all that important right now, but should be fixed if you want it RIGHT! :-)

I replace R36 with a 1W resistor, but that ceramic comp will run red hot without changing value, so not really all that important.

Your 220 mA is 144W input, which should give you about 79W output, right where I'd expect. That's good, although low. Perfect would be .340 on the PLATE meter, for 220W input, and about 122W output. You could load for more, but those are the design values.

A new pair of PA tubes, and a new R38 and you should be right on the mark!! Good work!

Alright Garey,
I went to change the tubes because there wasnt any difference. The suppressor came off in my hand so I am making some new ones. I have another fresh set of Sylvanias on the way and am hoping they are as good as advertised. I do have another set I can use for now. When I get it back together I will get on with what I was doing. I am using some ceramic comps to put the coil on they are smaller in diameter but equal in length so there will be a little gap between the resistor and the coil. Ive seen some of them be just loops so Im thinking this wont matter.

Ill read this again to make sure I follow what you are saying.
I was just able to neutralize the tubes so I will check the readings again.
I am pretty happy with the adjustments now, they look ok to me. I will take another look with the volt meter now and see if it changed anything. Ill get back to you on what I find.

OK, we were all where you are once upon a time! :-)

Your 6JB6s aren't too well matched. The 'fluctuating' reading on R33 is not good, and probably

indicates a flaky tube. If your 6JB6 tubes were 'matched', you would read 0.525 VDC across either 'perfect' 15 ohm resistor and the meter would read 70 mA of IDLE current. Right now, V6
is passing 33 mA of idle current, and V5 is only passing 27 mA for a total of 60 mA. You need
to select a new R38 value that will make the meter read 60 mA, then re-adjust the BIAS for 70
mA. Since the tubes aren't matched, one is handling 21.6W and the other is 17.6W for a total of
39.2W than the 45.5W, equally shared that it should be. This is not all that important right
now, but should be fixed if you want it RIGHT! :-)

I replace R36 with a 1W resistor, but that ceramic comp will run red hot without changing value,
so not really all that important.

Your 220 mA is 144W input, which should give you about 79W output, right where I'd expect. That's good, although low. Perfect would be .340 on the PLATE meter, for 220W input, and about

Ok now, Garey, I changed the tubes out but when I couldnt neutralize them I changed those out.
Now I cant find a sweet spot to neutralize these either. The voltage on the resistors looks good with these but its like the neutralizing cap isnt doing anything.

Am I going to have to change the suppressor resistors back to carbon?
I have a pair so I can do that, it was working before I changed those.
Ill see tomorrow, Im getting tired out tonight.

Heh...I saw that on eBay!

I sent a 'private' to him, questioning the price of shipping...and he also selling an MS_4...also ridiculous shipping...What was it...60 for the PS and 40 for the box....GAH! I won't bother to bid on either.

The MS-4 fits in a Regional Rate C box just fine...not much spare room, but we are only talking 5 pounds tops...he won't do it....BTW..shipping on that 'C' box from Merrick (I think that is where he is) NY to my home in Reno, Nevada, was only 19 bucks.

I think Paul K. has an AC-3 that I will buy from him...I need it so I can sell an Early Drake '4' set....T-4x and R-4A. Besides...I trust Paul! The guy on eBay..don't know him from Adam.....

Greetings Bill, wb9cac, I am ready to purchase your b line as long as the face plates are not scratched and the lettering and finish is not worn or faded. I'm not too concerned about the ms4 appearance, that can be refinished. Are there any known issues past or present. Just to recap, b line with cables, ac4 with upgrade, ms4, & a d104 mic for $450.00 plus shipping. Sounds good to me. Still would like to see a few pics. Let me know when you can.
Thanks Bill, Dave. W6dst. "73",

Sat May 24, 2014 7:10 pm (PDT) . Posted by:

<mailto:ralph.gent@...?subject=Re%3A%20TR4%20resistance%20chart%20measurement%20V19%20pin%202> stockman_11743

Garey:

Agreed, the V2 area is the one of interest. I did a double take and this time around measured the voltages at the pins. Both pins 1 & 2 showed about 200VDC (definitely no good) and when tapping the chassis the voltages would disappear. As I look at the schematic the only way the grids would get that kind of voltage is via the V2 plate. So I installed another 12AV6 (third one) and this time around all seems to be working correctly; initially that is.

Tuning up in X-CW is right on; however, when the relay returns back to RX the audio almost sounds as if sideband was changed even though lower sideband is lit on 40. Engaging X-CW a few times and sometimes the audio sounds correct and off sideband the next time around; I get the same effect switching the sideband function. I don't have another 12AV6 so I'll send away for a few and hopefully they will turn out good.

Thanks for your help, I'll report back when I get another 12AV6.

Thanks,
Bruno KC2ESI

Bruno -

OK. That 12AV6 isn't one of my favorite tubes... ! :-)

The Carrier Oscillator is shifted off frequency in CW by the small relay on the back wall
right
near the CAR OSC. Sounds like perhaps it isn't operating reliably. It's an interesting
circuit, the relay coil (12 VDC) is in series with the +150 VDC to the screen of V15. The
relay
is de-energized on SSB by shorting out the coil with switch contacts on the back side of
the
first wafer of the MODE switch. The switch is 'closed' (shorting out the relay coil) in CAL
and
SSB positions, and 'open' (causing the relay to close) and shift the CAR OSC about 1 kHz
up,
ONLY when the T-R relay is closed. Confusing, I know... Essentially the relay K2 (CAR OSC)
is
energized ONLY when CW or AM MODE is selected, AND relay K1 (T-R) relay is closed. When the
transmitter VOX releases, BOTH relays should de-energize.

Sat May 24, 2014 8:09 pm (PDT) . Posted by:

<mailto:vk2sja@...?subject=Re%3A%20TR4%20%20or%20TR4c%20%20Relays%20%20Replaced> "Steve VK2SJA" vk2sja

Hi Garey,

Very interesting.

I just checked my TR-4C S/N 36805. V19 is a 6EV7 and the circuit diagram I'm using from your CD is called "TR-4C Schematic 35161" which shows 6EV7. This is the correct circuit to be looking at, Yes?

However my installed relay is a 48vdc with 2.5k ohm coil. Early on when I had trouble with relays pulling-in I bought a spare. It is also a newer 48v 2.5k ohm coil. Since the new relay did not "fix" the problem at the time I back swapped to the original unit that was installed.

However I've just checked and I do NOT have a 1.5k ohm 1 watt resistor in series with the coil as shown in the later circuit called "TR-4C Schematic 42500". This circuit gives this resistor designation R194. (Which just by the way, is missing from the version of your TR-4C service guide I have. But paradoxically, the same guide lists R143 as the newer 330K and not the older 680K. Anyway no biggie but I thought I'd mention it in passing).

So assuming I have correctly got my head around all this. My questions are:

What effect/symptom is caused by running the rig with the 2.5k coil with R194 missing? As it begins to look like the previous owner replaced the original relay but didn't know to install R194.

Next question. Where did Drake install R194. At the base of V19 or behind the the relay on the relay PCB?

73, Steve

Garey, Bob is the person I bought the extender boards from. I did see
his AUX-7 article, but do not have the eyesight, patience, nor skill to
build one.

I'll send him an email and ask.

Thanks and 73,

Geoff.

Sat May 24, 2014 11:45 pm (PDT) . Posted by:

<mailto:pulsarxp@...?subject=Re%3A%20T-4XC%20PTO%20Spring> "L L bahr" pulsarair

I am in need of the long springs mounted on a C-line PTO for my T-4XC transmitter I recently acquired and am restoring. (Puts rear tension on the PTO shaft.) I've never needed one before, but it seems to me this was once covered as a topic and there was a source given. By chance was it maybe McMaster-Carr or maybe Small Parts? So head me in the right direction. Where can I obtain one?
Thanks,

Lee, w0vt

From: prosolar@...
Topic: 21173 Message: 21173

When I key the microphone, the s-meter on one of my tr4s moves along with the modulation. It's acting like the plate current meter.

I know the meters are known for going up scale, but I can't recall if they act like that.

anyone else notice this?

mike, wb8vge

21175. File - Bi-Weekly Statement

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-25 15:07:15 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 21175

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

21176. Re: [DrakeRadio] TR4 or TR4c Relays Replaced

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-25 15:15:02 UTC
From: Garey Barrell
Topic: 21148 Message: 21176

Hi Steve -

Yes, that would be the correct schematic for your radio.

A lot of people 'missed' the 1.5k resistor when the relays first started failing. I don't think
Drake even considered it for a while. Without it the 6EV7 (or 6FQ7) and relay are both overloaded. In the T-4X/B you can move the relay lead from Pin 1 to Pin 9, and then install the
resistor between Pins 9 and 1. Unfortunately, Drake 'used' Pin 9 in the TR-4C as a tie-point,
so it's not available.There is no 'good' place in the TR-4C. Unless you are running mobile, a
1W resistor lead is tough enough to just lift the relay wire from Pin 1 of the V19 socket, install the resistor, and reconnect the wire to the 'flying' lead of the resistor.

The parts list on the CD was for the s/n 38800 version of the radio, and the list reflects that. Since the photos are of the 38800, there is no R194 there either! I probably should add
R194 to the list and note 's/n 42500 version.

Without R194, the relay and tube are both overloaded, as described above.

R143 was changed before the tube was changed, and is to provide a bit more negative cutoff voltage to ensure that the relay drops out reliably.

Yes, that's the ALC indicator. It will read up-scale by 'some' not critical amount. IF it 'wiggles', it means the ALC is limiting the power. For the cleanest signal it's best that it
NOT wiggle. Increase MIC GAIN until it just wiggles, the back off just until it steadies or stops wiggling.

David -

Have you tried neutralizing on 15 or even 20M first?? The resonance is considerably wider there, and so easier to spot. Then can be refined on 10M when you're 'close'. You could also
use the 'PA Screen voltage removed/receiver or scope on the ANT output/tune neut cap for minimum' method!

The resistors shouldn't affect the parasitic suppressors. The coil around them though is fairly
critical. These are normally 'tuned' to resonate broadly at the frequency where the amplifier
tends to be unstable. This frequency is different for each amplifier configuration and depends
upon physical layout, lead lengths, etc., that cause the instability. I wouldn't think they would affect neutralization much if at all. Are the new coils essentially the same number of
turns, diameter and length??

I have another fresh set of Sylvanias on the way and am hoping they are as good as advertised. I do have another set I can use for now. When I get it back together I will get on with what I was doing. I am using some ceramic comps to put the coil on they are smaller in diameter but equal in length so there will be a little

gap between the resistor and the coil. Ive seen some of them be just loops so Im thinking this wont matter.

>

Here are a couple of thoughts after looking at the schematic:

The transistors appear to be drawn from the TOP view. This would
place the Gate on the left side, connected to the coil, where it
belongs.

I don't feel the connection shown between the transistor's center
pin (Source) and the junction between the two 4.7k resistors is
correct. It would elevate the sources of both FETs to +9v and
bias them OFF. I would eliminate it.

> 1. How many turns of what wire does one need to put on the
> loop?

That depends on a number of things, such as the permeability of
the ferrite, the frequency of interest, etc. The bottom line is
you need enough inductance to establish resonance at your
frequency of interest with the range of capacitance values
provided by the tuning cap.

> 2. It looks like the coils are shorter than half of the rod,
> and wound at each end, instead of one coil either spread out
> along the length, or in the center.

Ferrite rods work best in these applications when the length of
the coil is made small with respect to the total length of the
rod.

> 3. I have more than twice as many J310's as MPF102, would they
> work?

MPF102 have become obsolete. J310s are much better devices. You may need to decrease the value of the 1k resistor shown the schematic, as 1K may be too high for the J310s.

Finally, you don't need to use a ferrite loaded coil to build an effective H-Field probe antenna for use on LF frequencies. I typically use air-core coils wound from multi-conductor ribbon cable. These coils are typically several feet in diameter, and are hung from some kind of non-metallic support structure. I have found no need to electrostatically shield these coils, because I typically terminate them in high-Z balanced, differential amplifiers, similar to the Palomar unit referenced above.

And on much lower frequencies (60 kHz and below), I use an instrumentation amplifier, like an Analog Devices AD620, to buffer and amplify the output of the coil.

John is likely right. I found this diagram with Google,
but it appears to be drawn in error.
The + supply goes to ground via a diode drop and 1 KOhm.
That can't be right.
Anyone have the correct diagram?
Dave S.

Dave -

I think that part of the schematic is ok. That 'diode drop' and 1.5k resistor to ground is an
LED for power indication and would be correct.

John seems to be right on the FETs, this would be looking down on top of the device and the leads out of the bottom, Gate, Source and Drain.

Hi Garey:

I located another 12AV6; cleaned up the K2 relay contacts and gave the wafer switches another cleaning with DeOxit. All appears to be working as advertised.

I am without an antenna since Hurricane Sandy so I plan of dropping the rig of at my a friends QTH. He will run it through the bands and hopefully get good copy without any problems.

Thanks for the help.

Hi group. This does not belong here so I apologize in advance, but I don't know where to turn for help!

I have a FT-2000 + DMU and now my band scope has stopped working. It seems impossible to locate the needed spare part, a ceramic filter TOKO ALFYM455H=K, Yaesu part# H3900542. I have tried the most obvious, the local Yaesu delaer, and Yaesu (UK) to no av ail.

So, since the radio is almost vintage ;-) I decided to ask if anyone heler can supply such a filter, or help me get hold of one. Possible answers can be mailed to oh6nt@....

Sorry for the inconvenience!
/Tom

21186. TR7 Extender Boards

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-25 22:18:43 UTC
From: Don Cunningham
Topic: 20472 Message: 21186

Geoff,
If you haven't found any extender boards, get in touch with me off the reflector. For some reason, I cannot send you an email directly. I have a spare set of Bob's extender cards I have not ever used and have recently gotten a set of original Drake ones and Bob's set is available for another user. I also have some original service manuals I will sell if you are interested in one.

21187. DXing with my "new" 4 Line

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-26 02:25:03 UTC
From: rochep@...
Topic: 21187 Message: 21187

I have been having so much fun playing with my R4A/T4XB that I decided to use them in the WPX CW contest this weekend to try to boost my "Drake" DXCC total up from 70 worked (not bothering with confirmations). I USUALLY use either a Kenwood TS-850S or TS-590S and 400 watt amp.

What a PAIN to search and pounce with separate RX/TX, I was spoiled by the transceiver!! (Still cannot use the Drakes in transceive mode, I can not get used to listening with >1 kc offset instead of the 400 Hz I prefer). I would call a LOUD station that I found on the R4A over and over and over only to realize my TX was not ALSO tuned to that frequency. DOH!! Collateral damage of contesting, I guess. But I managed to work a total of 68 DXCC countries, so my "Drake DXCC" total is now 112. And I worked 35 zones, only missing 2, 27, 34, 36, 37, and 38 for my "Drake WAZ".

In crowded loud band conditions the 400 Hz LC filter just doesn't cut it like the crystal filters on my big rigs. I might buy an external audio filter to help out. Overall pleased I could work new ones, but a really rough way to make 150 QSOs. (I sent all CW by hand, but logged with the computer. That make things more difficult a BIT, but at least I did not have to keep a paper dupe sheet like in the old days).

21188. Re: [DrakeRadio] T-4XB BIAS SUPPLY

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-26 04:07:19 UTC
From: David Nichols
Topic: 21152 Message: 21188

Well Garey,
I did it again, when I was cutting the old suppressor out I also clipped the wire going down to the neutralizing cap off of the lug to V6. No wonder the cap didnt work. Thats what I thought, but I still dont have it. Still checking to see what else I might have messed up.

David - KX7C.

Subject: Re: [DrakeRadio] T-4XB BIAS SUPPLY

David -

Have you tried neutralizing on 15 or even 20M first?? The resonance is considerably wider there, and so easier to spot. Then can be refined on 10M when you're 'close'. You could also
use the 'PA Screen voltage removed/receiver or scope on the ANT output/tune neut cap for minimum' method!

The resistors shouldn't affect the parasitic suppressors. The coil around them though is fairly
critical. These are normally 'tuned' to resonate broadly at the frequency where the amplifier
tends to be unstable. This frequency is different for each amplifier configuration and depends
upon physical layout, lead lengths, etc., that cause the instability. I wouldn't think they would affect neutralization much if at all. Are the new coils essentially the same number of
turns, diameter and length??

> David - KX7C
>
>
>
>
> Alright Garey,
> I went to change the tubes because there wasnt any difference. The suppressor came off in my hand so I am making some new ones. I have another fresh set of Sylvanias on the way and am hoping they are as good as advertised. I do have another set I can use for now. When I get it back together I will get on with what I was doing. I am using some ceramic comps to put the coil on they are smaller in diameter but equal in length so there will be a little gap between the resistor and the coil. Ive seen some of them be just loops so Im thinking this wont matter.

21189. TR-4 RCVR PROBLEM

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-26 05:11:57 UTC
From: k5eh
Topic: 21189 Message: 21189

My TR-4, s/n 19360, gave up the ghost. Was working fb. Now, no rcvr
audio nor signal indications. Xmtr working fb. tcvr/rcvr sw in tvcr pos.
Tube ck ok on cker, with exception of V2, 12AV6.Also, doing voltage
checks note no cathode voltage on pin 2 of V2. Could this be the
problem? Comments?
Thanks, Jim, K5EH

From: w5rkl@...
Topic: 21189 Message: 21190

Have you checked for receive audio at the RCVR GAIN pot center terminal?
Have you also checked for receive audio at the grid (pin 1/7) of V17 (6AQ5)?

A scope set to measure AC connected to the 2 points mentioned above will show whether there is audio present or not.

If there is receive audio at the center terminal of the RCVR GAIN pot but no receive audio at the grid (pin 1/7) of V17 (6AQ5) then I suspect Q5 (2N3877) has failed. If Q5 fails then V17 will not produce any audio output at the speaker or headphones and the S meter will not function in receive.

The S Meter circuit uses the plate of V17, 6AQ5 audio output tube, as part of the S meter "Bridge" circuit (See the S meter function in the TR4's manual page 4-2).

Check the voltages at the Base, Emitter, and Collector of Q5 and compare them to the manual's voltage chart on page 5-5.

If V2, 6AV6, is weak or bad then the CW side tone and AM audio preamp circuit will be affected. I would replace V2 if it appears to be weak or bad.

Jim,

I may have mis-spoke about Q5.

What model of TR4 do you have?

If your TR4 is not a TR4C then Q5 is not used.

V-2 is the side tone oscillator. The cathode goes to
S-2 and is open in some positions. Other than the
Receive-Tranceive switch being in the wrong position the
most common cause of the receiver going dead is the "fuse
lamp" in the antenna. They can open or have corroded
contacts. I would check that, if you have not already,
before getting too deeply into other stuff.

Jim -

V2 Cathode is grounded only in CW, otherwise is floating. It is only active in AM for audio preamp. It shouldn't affect the AVC (S-Meter indication) which I'm guessing is what you mean
by 'no signal indications'. ?? Check Plate, Screen and Cathode voltages on V17.

Jim -

V2 Cathode is grounded only in CW, otherwise is floating. It is only active in AM for audio preamp. It shouldn't affect the AVC (S-Meter indication) which I'm guessing is what you mean
by 'no signal indications'. ?? Check Plate, Screen and Cathode voltages on V17.

21197. Not quite a Drake question :-)

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-26 20:37:15 UTC
From: Mark Pilant
Topic: 21197 Message: 21197

Hi Garey.

I recently acquired a Collins S-line (32S-1, 75S-1, 516F-2)
and have started to clean them up. I'm doing the 75S-1 first;
for no particular reason :-)

Anyway, it appears to have a number of modifications and I was
wondering if you knew of anyone who had something line your Drake
CD for the Collins line? (BTW, I have found your CD invaluable.)
It would sure help to determine what is stock and what isn't.

Thanks in advance.

21198. Basket Case Drake T-4XC

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-26 20:40:27 UTC
From: L L bahr
Topic: 21198 Message: 21198

I've been working on my basket case T-4XC. So far:
1. Cleaned the thing from top to bottom. It was really dirty but looks pretty good now. (I used Q tips and alcohol. A lot of Q tips!)
2. R epainted the meter bracket and dial hood white. Then re-installed the meter.
3. Cleaned and lubed all the pots
4. Checked the relay. (Its the old 15k Tyco one that has a habit of going bad. It's OK.)
5. Cleaned and lubed the adjustable coil rack mechanism.
6. Checked all the tubes and replaced three of them. (One was gas sey, another was wrong tube, and third one was weak. Not sure about the finals yet.)
7.   Found a replacement main tuning knob as original was missing.
8. Found a replacement meter lamp holder as original was missing.
8. Dug out a replacement top cover as original is badly dented.
9. Found a source for the L1 board because L1 which feeds 650 volts to the final plate choke is burned up. It's a 750uH three pi choke good for 300 ma. per Garey, K4OAH.
10. The PTO is a disaster. I need to totally rebuild it. The spring is missing as well as 5 ball bearings and the gears need shims to align it. McMaster-C arr can supply me with a new spring and I think I can buy the ball bearings there too but I need to buy 500 of them! Most likely I'll have to sand some plastic to get rid of some binding. One good thing, the clear plastic dials look good.
11. The front panel really cleaned up nicely.
12. I cleaned and re-whitened the knob hash marks. They look good as well.
13. The can electrolytic has leaked slightly so I need to replace it, but I would have done that anyway.
14. I spray pai nted the top of the stacked filters with aluminum paint as it really improved the appearance of the radio.
15. When I'm ready to fire it up, I'll install BLUE LED lamps as I have been using them on other Drake gear.
16. When I get everything put back together I'll have to trouble shoot any difficulties and do a complete alignment.
I've really taken a good hard look at the transmitter and everything else appears OK. I' won't know until I fire it up if it has any more maladies. O ther then that, she is a real cream puff! T he project has been a lot of fun so far. I've been doing things I have never had to do before when working on Drake gear. I can see when it is finished it will be a really nice T-4XC. I hope I won't have to work on it for the next 40 years.
Lee, w0vt

I've got to refurbish a T-4XC and a R-4C for my ham club, so this is good practice!

Hi Garey,
Well I got it figured out and playing again. It took a Different set of tubes but it is working and doing well now. I put the receiver next to it and played with them a little.

Still more to go but I couldnt help myself. I sent you a picture, might be at the bottom.

David - KX7C

Subject: Re: [DrakeRadio] T-4XB BIAS SUPPLY

David -

Have you tried neutralizing on 15 or even 20M first?? The resonance is considerably wider there, and so easier to spot. Then can be refined on 10M when you're 'close'. You could also
use the 'PA Screen voltage removed/receiver or scope on the ANT output/tune neut cap for minimum' method!

The resistors shouldn't affect the parasitic suppressors. The coil around them though is fairly
critical. These are normally 'tuned' to resonate broadly at the frequency where the amplifier
tends to be unstable. This frequency is different for each amplifier configuration and depends
upon physical layout, lead lengths, etc., that cause the instability. I wouldn't think they would affect neutralization much if at all. Are the new coils essentially the same number of
turns, diameter and length??

> David - KX7C
>
>
>
>
> Alright Garey,
> I went to change the tubes because there wasnt any difference. The suppressor came off in my hand so I am making some new ones. I have another fresh set of Sylvanias on the way and am hoping they are as good as advertised. I do have another set I can use for now. When I get it back together I will get on with what I was doing. I am using some ceramic comps to put the coil on they are smaller in diameter but equal in length so there will be a little gap between the resistor and the coil. Ive seen some of them be just loops so Im thinking this wont matter.

Hi folks,

Rummaging thru some of my stuff tonight, looking for some stored vhf gear, I came across a DC-3 Power Supply I didn't know I had !!

Not exactly sure at the moment how I come to have it, but I just wanna check if there are any real differences to a DC-4 (actually have a TR-4cw/RIT) which I wouldn't mind using it with.

Gary -

The only significant difference is that the DC-4 added a 115 VAC outlet to run a receiver, or
the Twins R-4/T-4X.

The DC-3 will run your TR-4C just fine.

I would go lower in resistance -- maybe down to 330 ohms. I would be more concerned with minimizing battery drain than optimizing IMD characteristics, because the Q of the loop will significantly limit the amount of extraneous signals that can enter the preamp, reducing IMD probability.

> And to keep it the least little bit on topic, am I correct in assuming
> that if I were to build a single, not split loop to those specs, and
> plugged it into the loop socket of the SPR-4, it would work?

I'm afraid not. The loop input to the SPR-4 connects directly to the emitter of an NPN transistor -- a VERY low impedance input -- AND the SPR-4 is looking for a low resistance DC path to ground from that input as well, AND it's shunted to ground with a 1000 pF capacitor, too!

You might get away by forming a series resonant circuit between your ferrite loops and your variable capacitor, but you'd also need to provide a DC path to ground across the this tuned circuit as well. Not that it's impossible -- it's just an added complication. But then your loop would no longer be balanced, and would become sensitive to E-fields, and this would degrade the SNR.

I think you would be much better with your first approach: Obtain resonance through parallel (variable) capacitance across the loop%

I'm afraid not. The loop input to the SPR-4 connects directly to the emitter of an NPN transistor -- a VERY low impedance input -- AND the SPR-4 is looking for a low resistance DC path to ground from that input as well, AND it's shunted to ground with a 1000 pF capacitor, too!

You might get away by forming a series resonant circuit between your ferrite loops and your variable capacitor, but you'd also need to provide a DC path to ground across the this tuned circuit as well. Not that it's impossible -- it's just an added complication. But then your loop would no longer be balanced, and would become sensitive to E-fields, and this would degrade the SNR.

I think you would be much better with your first approach: Obtain resonance through parallel (variable) capacitance across the loop, buffer the output through a high-Z balanced differential amplifier, and feed the low-Z unbalanced output of the buffer directly to the SPR-4.

But I'd also check to see what value of DC resistance the SPR-4 needs across it's loop antenna input terminals, too, and incorporate that into your loop preamp circuit as well.

BTW, you can find a nice balanced LF loop preamp circuit using J310s here (down at the bottom):

http://www.lowfer.us/k0lr/bal-pre/bal-pre.htm

It uses a 2N2222 as a constant current source in place of a resistor in series with the J310 sources, and it uses varactor diodes to electronically (remotely) tune the loop. Should serve as the basis for what you're trying to do.

What Glen said.

I've been using a DC-3 with the mobile TR-4 for several years now. Had to replace the diodes last year (would recommend doing this, the old ones are weak) after one blew, and checked out all the caps. Not a single one had appreciable leakage!

They are a bit noisy and get VERY warm, but the DC-3 is a nice little supply!

Jim -

Does the relay click?? Same on more than one band?? Change sidebands?? ANY S-Meter indications??

If you don't have known good tube spares, try swapping V3 with V18. If no change, swap back and
then swap V7 with V12. If no change, swap back.

I know you intended this to be off line but I'll be happy to offer up a few comments. I am not aware of any K4OAH style CDs for Collins. Google Hi-res Communication, Flloyd Soo, and he offers a complete line of video DVD's documenting experts (and I mean the top dogs) repairs 32S, 75S, 30L-1's, etc, including PTO rebuilding, aligning. The Collins Collectors Association at collinsradio.org has a large online collection of manuals and service bulletins for S-line radios. You might consider joining subscribing to the CCA reflector and asking this question about mods and if some mod summary exists somewhere. I know Electric Radio has some Collins mods stuff for sale in the back but I only remember the 75A-4, not sure if there are any S-Line mods.

Charles - We (the Left coast) also have the Vintage SSB Roundtable on Tuesday evenings, 3.895 +/- around 1900 local. Usually a few Drakes on there. It's a lot of the same guys from the Friday night Collins net. Mark

BTW, they have a Yahoo group too.

Mark J Dossett / K6MJD / San Diego
---
www.k6mjd.com

It would be nice to see something get started here on the left coast.

We have a nice group of operators that have a Collins Net on Friday evenings. True, not much discussion about the radios, but a nice time is had just the same. Gives everyone an excuse to fire up the rig.

Just an idea....

I have a lead on a person that is supposed to have made a similar item to Garey's CD. I have sent an email and am awaiting a reply.

I've been on the Collins reflector for a couple of months now, so I need to post something there as well. I just figure with the high quality of Garey's CDs, he'd probably know of someone doing something similar. (I can't imagine there's a lot of people doing it. :-)

Topic: 21216 Message: 21216

R-4B Alignment

Ok??? What did I miss?
Im at the 50 KHz I.F. step, 6.4.3
I have done steps, 1,2,3,
No can do step 4... my signal gen is maxed out (set to 0 dBm) and I cant hardly work up an S1 signal level. S9 seems like its unattainable. I begin to hear the signal at about the -20 level and I can hear it pretty good at "0" but no S meter movement.

I thought, well, maybe I can get a signal if I adjust and build it up but I really didnt find anything to work with. So I have adjusted T7/T10 looking for an indication and finding none. I was able to increase the voltage a little with T14 but that didnt help me.
OH! May be related??
In the previous step, the 50 KHz Osillator
I attached the alignment load and then turned on the calibrator. I could hear the note until I turned on the Calibrator. When I turned the calibrator on I could not hear any notes. (the calibrator seemed to mute the receiver) I played with the adjustment and got a signal I could sort of work with.
The 25 KHz went slick and things slid down hill from there.

David -

Did you capacity couple the generator to Pin 5 of V5??? 0 dBM should blow the doors off.....

TP-3 is the wire jumper across the CAL board. I think you have a counter, so connect it to one
of the leads of T11. With the CAL ON, you should see a huge signal at 50 kHz. Adjust T11 for
exactly 50.000 kHz. 6.4.3.4 just has you beat the second harmonic of the 25 kHz CAL output against the BFO. The point is just to get the BFO ON 50.000 kHz.

OK. too late at night!!

The CAL should be OFF for this test. You are mixing the 5645 kHz with the 5595 kHz in V3, and
zero beating the 50 kHz output against the BFO. Should occur right on 5645 kHz on the generator, and NOT take a whole lot of signal. This is where a received signal gets downconverted to the 50 kHz IF.

Ok, that will make things a lot easier for sure,
I have an idea, how about you rewrite the instructions in todays language and instruments.
I would buy a copy for sure. It was a lot easier getting 50 KHz your way.

From: Garey Barrell
Topic: 21216 Message: 21221

David -

You have to remember that most hams didn't have that kind of test equipment in the mid 60's.

The best thing that happened to hams was when all of industry switched over to automated test
equipment, resulting in tons of high quality HP, TEK, GR and other gear that couldn't support
ATE hitting the market.!!

21222. Re: [DrakeRadio] TR-4 RCVR PROBLEM

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-28 04:03:28 UTC
From: jim lewis
Topic: 21189 Message: 21222

Garey,

Yes, both relays click on 40, lsb and usb. I haven't tried other bands. I am using the setup in the manual for resistance and voltage checks. All tubes cked ok on checker, but will do the tube swap thing. Thanks for responding, again.

73, Jim, K5EH

Jim -

Does the relay click?? Same on more than one band?? Change sidebands?? ANY S-Meter indications??

If you don't have known good tube spares, try swapping V3 with V18. If no change, swap back and
then swap V7 with V12. If no change, swap back.

Garey,
I am beginning to suspect the PTO. I cannot hear the pto on my aux rcvr when I sweep the dial. I can, however, hear the 9mHz osc. shouldn't I be able to hear the pto on another rcvr?

Thanks, Jim, K5EH

That explains a lot of things to me. In a previous home, our backyard
was on the end of a nature preserve. Our fence was 11 meters from the
building, enough to be out of the noise cloud. A coax loop made from
RG-6 to the specs of loop sold with the SPR-4 worked well. The original
drake loop was made with RG-174, connected to ground at one end (and the
amp at the other). This one was hung on the fence, and wired the same
way, with about 15 meters of RG-6 coax in between.

With it I was able to pull in the BBC station on 648kHz. It was mostly
noise, but there. I did not know they were about to shut it down, so I
did not record it. :-(

> I think you would be much better with your first approach: Obtain

>
>
> --

>

Thanks, I'm attempting to obtain one. While I am waiting I finished a PA0RDT sort of loop. I did not have 2n5019 transistors, so I substituted a 2n5179. So far it works, but I have only tried it indoors and it just amplifies the noise.

Geoff.

21225. AC-4 Power Supply and T-4XC Update

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-28 05:37:02 UTC
From: L L bahr
Topic: 21225 Message: 21225

Did Drake ever actually print a circuit diagram for the AC-4 Power Supply containing the 110/220 switch? I sure would like to find a copy for my records. The reason I ask is I acquired an AC-4 having the slide switch holes punched into the chassis yet the power supply was factory wired as without the switch. (The chassis never had a slide switch mounted on the chassis.) The chassis does not have the 110 and 220 volt markings on it either, just the holes for the switch. I've decided to add the switch which is simple enough to do. I've figured out how to wire it but will have to lengthen a couple transformer leads to do it. It would be nice to have a factory diagram showing the switch. However, I suspect Drake actually never produced such a diagram to the general public.

As for the progress on my T-4XC, I'm waiting for parts. I ordered ball bearings for the PTO as well as the missing PTO tension spring. The PC board containing RF pi choke L1 had L1 fried so I have a complete replacement board coming as well as some high current pi chokes to rebuild the existing board if I don't make use of the new board coming my way. (It amazes me Drake used such a small current handling choke to pass 300 ma through it.) At any rate I can solve the burned up choke problem with either solution. I am leaning towards rebuilding the old board with one of my high current pi chokes as I am not impressed with the Drake specified compon ent. I'm also waiting for a replacement can electrolytic to show up too. (I fully intended to replace the can electrolytic, just for drill, but this one needs to be replaced anyway because beetle ju ice is starting to come out of it.)

I guess while I am waiting for the above to show up I could start replacing the final screen and cathode resistors. Maybe even pass some time and build up new parasitic chokes for the finals.

Topic: 20718 Message: 21228

Hi Garey,

I have cleaned the band switch, replaced V2 with an 6EA8 and checked the 50 kHz and 405 kHz oscillators with a frequency counter. They are spot on, and The Passband Tuner is in the right position. Using a signal generator I have checked sensitivity, and there is still a clear lack of sensitivity on 80 and 20 meter. I have S8 on 80 meters and S7 meters on 20 meters, but S9+10 on 40 meters, where the receiver works absoutely fine. So what to look for next?

Jim -

The same PTO is used to transmit and receive. I think you said transmit was ok??

You should be able to hear the PTO (5.5 MHz at 000 on the dial), the BAND oscillator on 21.5
MHz, and the PreMixer output at 16.0 MHz.

Topic: 20472 Message: 21230

AUX-7s show up now and then on eBay, but they command a premium price. The most cost effective way to find one is in a radio. There are no kits that I know of.

Jim and the group,
OH yes there is..... !

I believe it was July 1982 issue of QST that had an article titled "WARC and LF for the TR7"

In any case there is a printed circuit board which is still available from a vendor. I'm sorry but the name escapes me at the moment...he was at the Dayton Hamvention again this year as normal. I'm looking at his tent in my mind.

As you have mentioned in the past it only uses eight resistors and about 32 diodes....the cheap ones.... HI
The hard part was the connectors which I did obtain through Mouser (but have a real thing source much less expensive)
The real thing connectors do NOT have to be bent around to use fwiw.

When I get home I will reiterate who the PC board vendor is.....

The circuit board company is probably FAR Circuits.

Carl,
It is FAR Circuits of Dundee, IL fame. I don't know of his PC Board
quality, but he does still show the kits and somewhere in my "archives"
I have the article. It sure looks simple to replicate, and would be a
neat project.

BINGO!

Now all I have to do is convince him to send one to me (his web page does not mention international shipments. :-)

I also have to figure out how to get the connectors.

Thanks and 73,

Geoff.

From: Garey Barrell
Topic: 20718 Message: 21234

Peter -

Interesting problem.... Remember that the 2-B is basically an 80M receiver with two RF stages,
that covers all the other ranges by converting the 2nd RF amplifier to a Mixer/Oscillator. This
is the 6U8/6EA8 stage, V2. So essentially the receiver from V3 on is an 80M receiver.

You say it is insensitive on 80 and 20. On 80M V2 is an 80M RF AMP, while on 20M a crystal oscillator at 18.0 MHz (the triode section of V2) injects a signal into the Pentode RF amplifier
section which becomes a Mixer, outputting 3.5 to 4.1 MHz for 14.5 to 13.9 MHz coverage. Obviously V2 is a potential source of trouble, but I don't follow why it doesn't work well on
80M yet works fine on 40M.

V1 covers 3.5 - 30 MHz by tuning the PreSelector. If you are satisfied that your 6EA8 is 'good', I would suggest following sections G and H of the Alignment Procedure from the manual.
C5 and of course C6 will affect 80M sensitivity, and L10 for 20M and up.

Let us know what you find. Also don't forget that there can be considerable differences between
the CALibrator output from one 100 kHz point to the next.

> Hi Garey,
>
>
> I have cleaned the band switch, replaced V2 with an 6EA8 and checked the 50 kHz and 405 kHz oscillators with a frequency counter. They are spot on, and The Passband Tuner is in the right position. Using a signal generator I have checked sensitivity, and there is still a clear lack of sensitivity on 80 and 20 meter. I have S8 on 80 meters and S7 meters on 20 meters, but S9+10 on 40 meters, where the receiver works absoutely fine. So what to look for next?

21235. Humming filament transformer L4B

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-28 20:44:52 UTC
From: handla@...
Topic: 21235 Message: 21235

Hello folks. Just get my hands on a L4B and have started to "test drive" it a little. When I start up the amp I have a humming noise (vibrating sound) from the area around the filament transformer. Just want to check if anybody know if this is a common problem on the L4B. After about 5 to 10 minutes the sound is gone and everything is normal. The sound can maybe come from the fan motor but I have tried to check that but next thing to do is to disconnect the motor and start up and listen. I am from Sweden so we have 50 Hz not 60 in our AC.

Anyone with some idea?
Regards from Sweden

Jan SM5SUH

21236. T4XC No CW output

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-28 22:41:17 UTC
From: tjb813@...
Topic: 21236 Message: 21236

I started with a basket case T4XC. Fixed the vfo. Then I fixed the HET oscillator. Then the Carrier oscillator needed some encouragement. Now I get a signal into T14 can, but nothing out. Its the balanced modulator. There should be a dc voltage to upset the modulator so the Carrier can pass through. I think the voltage from the Gain control is too low. Does anyone know what voltage should be put on the diodes in T14 for CW? I would assume it should be at least afew volts. I get 50mV from the Gain pot. All of the switches and knobs are in the correct position. The relay closes (when I key) and I get voltages on V2 right on target.

I guess I'm going to need Garey's CD to figure out where all of the resistors are. Difficult to trace them through. This transmitter was a $10 parts unit from Dayton and I'm really enjoying digging into it. I will enjoy using it with my 2B when it finally works.

Thanks in advance for the help

KD8CN
Tim

From: David Nichols
Topic: 21237 Message: 21237

Antenna, R.F., and Injection Circuits
Locate S5C and S5D (the third and fourth bandswitch wafers from the front)
Two rotor contacts are colored GREEN, connect a 10K ohm resistor to ground and another 10K resistor to B+. I "THINK" I see a couple of green contacts, looks like corrosion to me.
When I do this, I really want to be sure Im doing it right. I have made to many errors lately.
Looking from the front at the third wafer back. I think the contact I want is at about the 8 oclock position just below the screw head.
Looking from the rear at the fourth one back. I think the contact is at about the 4 oclock position just below the screw nut.
Can anyone either confirm my belief or straighten me out please.
I will make sure these are undeniably green when I find the right ones.

Jim -

The same PTO is used to transmit and receive. I think you said transmit was ok??

You should be able to hear the PTO (5.5 MHz at 000 on the dial), the BAND oscillator on 21.5
MHz, and the PreMixer output at 16.0 MHz.

David -

These are the 'wiper' contacts, which are the longer ones. They reach farther toward the center
of the wafer, so they are ALWAYS in contact with the switch segment(s). The 'green' is getting
a little faded on them by now, but if you look at the 'length' of the contact you'll see the
difference.

Ok Garey, thanks.. those are the ones I was looking at. They made more sense to be the ones and they have some light green color. I had noticed the color before but thought it must be some corrosion. The way I have been messing things up lately I decided I would wait and see if someone else would let me know if I was on the right path or not. The only good thing about the mistakes I have made is that I have been able to recover.

I had noticed the color before but thought it must be some corrosion. The way I have been messing things up lately I decided I would wait and see if someone else would let me know if I was on the right path or not. The only good thing about the mistakes I have made is that I have been able to recover.

dont remember clearly but I think there are 2 feedthru capacitors for the filaments, I remember having some problem and it ended in one capacitor starting to short, try disconnecting them from the transformer and see if theres some change also check these capacitors.

I wonder what the resistors are for? The band select logic on a real AUX-7 has no resistors. The only resistors on the board are part of the fixed-frequency crystal oscillator and crystal select circuit.

1N4148 is commonly used for the diodes. Any silicon that you have on hand will work. Although 1N540x would be overkill....

2C/2CQ and 2NT in excellent condition available for $900 plus shipping from 22554. Includes calibrator in 2C. Will ship double-boxed in three packages. Works great and hate to sell but I can use only so many radios! Also have stock R-4C for $350 plus shipping and stock T-4XC for $275 plus shipping. I have a 2BQ in good shape for $150 plus shipping. Selling because I am reducing my Drake "inventory". Contact me outside of the reflector with questions.

From: rochep@...
Topic: 21246 Message: 21246

I am using my R4A/T4XB in "separates" mode, have the FUNCTION switch on the R4A to external mute, and use the SPOT position on the T4XB so my TX frequency matches my RX frequency. That is all fine, but when chasing weak DX my GAIN controls on RX are pretty high, and when I go to SPOT to bring the TX VFO to my listening frequency the volume of the TX oscillator nearly blows my head off! Of course I can turn down RF or AF gain so this does not happen (and then when I am on frequency turn them back up again), but what a pain.

This is NOT the same as the sidetone volume. Is there some way to decrease the intensity of the SPOT signal (other than move the TX farther away from my RX)?

Jim,

The 8 resistors are 100k pull-down resistors. The diodes are spec'd as IN914.

I am not familiar with this particular transformer but
humming or buzzing can be caused by the laminations being
loose. If the transformer has bolts accessible try
tightening them. Also check that the mounting bolts are
tight. The fact that it changes as the transformer warms up
also suggests it may be mechanical.

Fellow Drake Enthusiasts,

I've not encountered a humming filament transformer but have experienced hum due to the blower motor/mounting or cabinet top. If it were me, I would disconnect the transformer or the blower motor and see which one is at fault before proceeding with the appropriate fix. Sometimes, but not always, using your hands to flex the rear panel or top cover can be used to fault isolate the problem component. If the slight pressure/flexing changes the sound of the hum, then it is likely due to the blower motor/mount.

Please keep the group informed of your progress.

Hello again. I have disable the crowbar for the high voltage so I can “poke around” in the amp when its operational and now I know that the sound not coming from the transformer. It is the fan motor that deliverers a low frequency vibration but I have not yet locate where the actual sound is generated. I wonder if the vibration is worse when the amp running on 50 Hz instead of 60?

Thanks for the comments regarding this topic. I now hope that I will find what chassi part

that make this sound the first 5 minutes of operation...

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-29 18:13:06 UTC
From: Garey Barrell
Topic: 21236 Message: 21251

Tim -

You should read up to a half volt or so on the BAL MOD DC input. There are two diodes in series
to ground (part of the diode quad mixer) that are forward biased. These are typically
Germanium diodes, so typically 0.2 - 0.3 V per diode.

Resistors R104, 105 and 106 are the source of this positive voltage, with R105 being the 'front'
part of the GAIN control.

Do you get output in AM MODE?? The BAL MOD gets a fixed DC voltage in AM from R103, and should
produce a 15 - 20W carrier output with no modulation.

Does it work in SSB?? The DC voltage comes in on the same coax as modulation for SSB, so can
eliminate the coax (short, open, etc.) as the source of the problem. If you disconnect the coax
at either end, you should get about 0 - 1.5 VDC 'unloaded' from R105 wiper.

There is a not too common problem where the diode(s) (located INSIDE T14) short to the can, or
of course one or more diodes can short.

Let us know!!

tjb813@... [DrakeRadio] wrote:
> I started with a basket case T4XC. Fixed the vfo. Then I fixed the HET oscillator. Then the Carrier oscillator needed some encouragement. Now I get a signal into T14 can, but nothing out. Its the balanced modulator. There should be a dc voltage to upset the modulator so the Carrier can pass through. I think the voltage from the Gain control is too low. Does anyone know what voltage should be put on the diodes in T14 for CW? I would assume it should be at least afew volts. I get 50mV from the Gain pot. All of the switches and knobs are in the correct position. The relay closes (when I key) and I get voltages on V2 right on target.
>
> I guess I'm going to need Garey's CD to figure out where all of the resistors are. Difficult to trace them through. This transmitter was a $10 parts unit from Dayton and I'm really enjoying digging into it. I will enjoy using it with my 2B when it finally works.

Jan,

When I come across this problem (have had about 4 cases of it) I found that it was a trial and error process to fix it. I believe the cause has something to do with loose mounting hardware, slight dimensional changes due to heat, etc. etc. To fix it, I loosen the hardware that attaches the brackets to the rear panel, then I move the the whole assembly slightly (direction is not important), and then retighten the hardware. Sometimes it works on the first try, sometimes the second, sometimes longer.

I found that working on it was best accomplished on my workbench. I would disconnect all the cables from the RF deck, remove the tubes and chimneys, CAREFULLY with protective eye wear, and disconnect the fan leads and use jumper leads to power just the fan, not the transformer, etc. etc. However, your amp might be modified or different in some way so please proceed with extreme caution.

73,

Evan

Ditto what Evan said?.exactly the same procedure I?ve used to cure my fan vibration, although on my original fan I just couldn?t seem to get rid of it. I ended up buying a used fan on eBay but in time it developed similar vibration.

As Evan says, it?s trial and error and I found that the internal brackets are probably the culprit. You might try first loosening the back panel screws and retightening them?.that worked for a while once on mine but in the long run opening it up and playing with those internal brackets is what quieted it.

Once you have it nice and quiet then gingerly put it back together to maintain that orientation; doing other maintenance on the amp can upset it and it?s very frustrating when you pack it back up and the darn vibration is there again. So I?d recommend if you gotta take it apart to just bite the bullet and check to see if the vibration is there by powering it up separately before reassembling it. Yeah, it?s a pain in the butt but not as much as having to take it apart and put it back together repeatedly.

And actually the real reason it hums is ?cause it doesn?t know the words?.so sorry, just couldn?t resist! ;-)

914s will work if you have them. Otherwise, I would go with 4148s. They are common as dirt and cheap.

The resistors are still a mystery to me. They duplicate what is already present on the Digital Control board, and so aren't needed at all. If I go ahead and get a couple of these to finish out my radios I will leave them off.

Jim,
The article said early TR7s didn't have them. loose quote, no harm in putting them in anyway.
As far as the PC board ...short memory FARcircuits .com I think
Carl WD8nhk

The resistors are still a mystery to me. They duplicate what is already present on the Digital Control board, and so aren't needed at all. If I go ahead and get a couple of these to finish out my radios I will leave them off.

Hmm, that's the first I have heard of that. I didn't read through the whole article. I'm dealing wiht an abraded cornea right now, and reading is a bit of a chore. Easy enough to check, the DC board is right there next to where you plug in the AUX-7. If it has the resistors there is no need to populate them on the FAUX-7.

Hello All,
Well, Im thinking my R-4B isnt hearing like it should.
I just did my first alignment on it. I like what I hear with the Passband selector on 4 but when I step it down to 2, I almost cant hear the signal anymore. It really drops down, now Im talking about receiving a signal with the antenna. I would expect to hear a little less but not such a big drop as I am getting.
So, which step didnt I perform correctly?
Is there a better way to balance the Passband than trying to match the pitch? I am getting the same thing with the R-4B as I got with my TR-4CW one side is noticeably louder and my ears just dont hear a matched pitch at any adjustment point.

Jim -

Hope your eye(s) recover soon!! Did we do something 'less than smart' and get caught? Safety glasses?

I'm almost recovered from my surgery, so we'll be up to fighting condition soon..... :-)

The 1N914 has been around for many years, and was the 'defacto' diode back in the 60's..... The
1N4148 came much later, and I don't really know the difference. I suspect it is the same die,
but a different packaging/sealing/manufacturing process of some sort. The 1N914 may have had
different lead material.... The 1N4148 came out before the 'lead-free' crap started so don't
think that's it. We used to spot-weld 'cordwood' modules with 1N914, so they may have had some
nickel or 'duvet' in the leads.

Same-O.......

Mis-aligned Passband Tuner probably. Remember the center between the dots is zero beat, and for
CW you should be nearer to one of the dots unless you prefer a low beat note, in which case you
may be closer to the middle. When you switch to 0.4, you have to repeak the Passband control.

If you have a good noise generator, (Palomar Noise Bridge, etc.,) you can view the audio output
with one of the PC audio spectrum analyzers and 'see' the passband as you adjust. Generally speaking, if you set up the mechanics properly, and center the Passband while peaking the slugs
on 0.4 kHz, you should come out pretty close. Make sure the NOTCH is OFF.

Normally the you should lose less than an S-Unit from 4.8k to 0.4k B/W.

Ok I am back at it, picking up at Passband tunner step 2.
When I adjust the little screw on the back of the passband tuner box I can hear some buzzing in the speaker. I can make it louder and weaker with the adjustment but it wont go away.
I have determined that if I touch the 12BE6, V3 tube it really comes in. (I know, dont touch it) hi hi
Another thing I have noticed since I did this alignment, when I first turn it on the S meter heads up scale and jogs back a bit and then heads back up scale before settling down on zero.. is this strange?

David -

Generally speaking it's best to leave that screw alone. It rarely gets out of place unless someone has been twisting on it! :-)

It's difficult to adjust the first few times you do it. If you don't have test gear, you can
recover it by rotating the Passband tuning knob from one dot to the other on 2.4 kHz b/w. What
the screw does is move the entire Passband up or down in frequency, so you can set it in the
middle of the 6 kHz 'roofing' filter and preceding transformer bandwidths. The 'hiss' on either
side never sounds 'exactly' the same, but is similar in 'pitch' when it's right.

The other approach is to tune through the CALibrator signal on 4.8 kHz and note the S-Meter as
you tune across. You should hear the beat note out at 2.5 khz or so, and as you tune through
zero beat and out the other side the tone should be the same frequency on either dot of the 4.8
line.

Hello Garey,
Well I have a bunch of test gear, I may not know how to use it to the fullest extent but I can follow instructions. I have been thinking that IFR service monitor should be able to do this if I was smart enough to know how to use it. It has the tracking gen and all but I have never used it.
I have been installing the new filter cap in the T-4XB while I waited for someone to answer me on this.

I do have a Palomar noise bridge and I even found it. Oh, that little screw on the back has been everywhere it will go now so I "need" to fix that little thing. hi hi

I can always count on a rocket scientist for an answer that at least sounds reasonable.

Got in a little argument with a mulberry sapling that was getting too chummy with one end of my 80 Meter dipole. It fought back. I won. Well actually, N0QYP and his tree cutter had the final say.

My glasses do have safety lenses in them, but it snuck around the side with a left hook.... The other eye is fine, it's the integration that sucks. Doc says I should be healed up in 24-48 hours. I can see well enough to solder, as long as it's not SMT. I'll decide in the morning if I stay home from work another day.

Not that WikiPedia should always be treated as Gospel but...

"The 1N4148 replaced the 1N914[citation needed], which had a much higher leakage current (5 microamps vs. 25 nanoamps). Since leakage is almost never a desirable property, today manufacturers produce the 1N4148 and sell it as either part number.[2]"

And apparently the 1N4148 has double the forward current handling capabilities of of the 914. 914 at 75mA, and the 4148 has 150mA.

Subject: Re: [DrakeRadio] Humming filament transformer L4B

Ditto what Evan said?.exactly the same procedure I?ve used
to cure my fan vibration, although on my original fan I just
couldn?t seem to get rid of it. I ended up buying a used
fan on eBay but in time it developed similar vibration.

As Evan says, it?s trial and error and I found that the
internal brackets are probably the culprit. You might try
first loosening the back panel screws and retightening
them?.that worked for a while once on mine but in the long
run opening it up and playing with those internal brackets
is what quieted it.

Once you have it nice and quiet then gingerly put it back
together to maintain that orientation; doing other
maintenance on the amp can upset it and it?s very
frustrating when you pack it back up and the darn vibration
is there again. So I?d recommend if you gotta take it apart
to just bite the bullet and check to see if the vibration is
there by powering it up separately before reassembling it.
Yeah, it?s a pain in the butt but not as much as having to
take it apart and put it back together repeatedly.

And actually the real reason it hums is ?cause it doesn?t
know the words?.so sorry, just couldn?t resist! ;-)

David -

Well, I've never had an IFR, so can't help there. You mention tracking generator, so it may perform as a spectrum analyzer and would be good.

Ideally what you want to do is to scan a signal across the bandwidth of the tracking filter.
Easiest would be a signal that would sweep from say 5.640 to 5.650 MHz, along with a 'receiver'
that is scanning 45 to 55 kHz in 'sync'. Ideally, that receiver output would be applied to a
scope screen to register signal strength vs amplitude. The resultant 'picture' should look something like the filter passband picture on page 22 of the manual. As you adjust the Passband
tuner, the size, shape and position of that plot will change, and you just continue adjusting
for that picture.

The Noise bridge and AF spectrum analyzer method works in a similar fashion, except the noise
bridge puts a 'white' noise into the front end, which is essentially 'filling' the receiver passband with a constant 'hiss' across all frequencies. This 'flat' noise signal is shaped by
the filter passband(s) and is output is therefore shaped like the passband. The 'analyzer', something like 'Spectrascan' software or similar can display this shape on the PC screen.

I 'think' the IFR can do something to accomplish this task, but I have no idea how to do it.
Perhaps someone on the list can help??

I'm working on a project called the 'Poor Ham's Simple Network Analyzer'. It uses a couple of
Chinese modules to build a 1-30 MHz signal generator that can be swept over any specified range,
and an RF detector with a logarithmic output covering a range from +10 to -80 dBM. It works great for scanning a crystal filter and making a list of amplitude vs frequency that can be plotted using Excel or other similar program. The other part is a 'Network Analyzer Terminal'
which is a device that uses a display like a cellphone that controls the PHSNA and plots the
output on screen. Currently it can make a scan for each press of a space bar, which takes about
a second, but software is still under development to make it capable of scanning continuously,
like a spectrum analyzer. PC boards are available for the PHSNA, (less than $100 total cost),

and a kit is available for the NAT for $65. More info at the 'PHSNA' Yahoo group.

21273. Re: [DrakeRadio] R-4B receive??

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-30 14:09:37 UTC
From: Paul Christensen
Topic: 21260 Message: 21273

If he has access to an IFR SM with tracking generator, it would work well for mechanical and crystal filters but likely not for L/C filters in the 50 kHz range. As I recall, most IFR models generate RF down to about 250 kHz. What I don't know is if the receiver/spectrum analyzer works down to 50 kHz. That would be important to carry out the test Garey describes below. Res. bandwidth on these service monitors is pretty awful for measuring close-in carrier performance but should be perfectly adequate for response sweeps.

PC-based VNAs are pretty cool for this application -- once you get past the software learning curve.

Probably the fastest and easiest method for a one-time job is Garey's suggestion of using an inexpensive noise bridge and PC with audio FFT software.

Mike -

Possibly bad filter. Also possibly dirty switch contacts.

Best check is to tune through the Calibrator signal, noting where the signal drops by one S-unit
at the highest and lowest frequencies. If these are not ~500 Hz apart, or the signal amplitude
changes considerably between these two points, you probably have a failed filter. IF this test
looks good, it's more likely a dirty switch contact(s) or other 'mechanical' problem.

Haven't tried am or SSB. I have not been able to locate R104 or R106 yet. I need your CD. I just haven't got around to ordering it yet. I did trace the shielded cable to mode switch and traced it to the wiper of R105. I suspect there are alot of out of spec resistors in this rig. Having a blast with this one. Haven;t had this much fun since I took a literal basket case TR3 that the owner said was junk and re-built it. He loves it now. With good info these are pretty easy to fix. Thanks for the help.

Mike,

Sounds to me like the radio might need an alignment and/or the 500 hz filter has gone south. What might be diagnostic is to examine performance on all bands to ensure it is not band specific. If it were me, I would activate the calibrator, tune back and fort across it and draw a plot of signal strength as a function of frequency. Then, I would switch in the 500 hz filter and do the same thing and plot it as well. If the filter has degraded, and/or the radio has taken the signal outside the centered passband, then severe degradation might be experienced.

However, I haven't owned a TR-4 in over ten years so my experiences with it have faded. Please keep us informed of your progress.

73,

Evan, K9SQG

Tim -

Switching to AM will give you a reference point. IF the carrier output is present, the problem
may be in the R104/R106 area. If NO output in AM the problem is elsewhere.

These resistors are on the Relay board, just alongside the right side of the relay.

> Haven't tried am or SSB. I have not been able to locate R104 or R106 yet. I need your CD. I just haven't got around to ordering it yet. I did trace the shielded cable to mode switch and traced it to the wiper of R105. I suspect there are alot of out of spec resistors in this rig. Having a blast with this one. Haven;t had this much fun since I took a literal basket case TR3 that the owner said was junk and re-built it. He loves it now. With good info these are pretty easy to fix. Thanks for the help.

21281. PHSNA Scan of TR-4CW filter

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-30 21:22:06 UTC
From: Garey Barrell
Topic: 21278 Message: 21281

I just posted an image of the passband of the 500 Hz filter from a TR-4CW. File name is 9-500.PDF

This was generated by the PHSNA device(s) I mentioned earlier.

Don't be too critical, the individual oscillator/detector/filter is spread out on the bench, no
shielding, no boxes. Clip leads for interconnect! Hardly a recipe for great stop band results. The detector sits at about -50 dB from random pickup (0-500 MHz).

But with a little more work, this could be a very handy tool.

I had the same issue with my B-line. I built a 20DB PAD and installed it in audio line. This dropped down the level of the SPOT tone and I turned up the AF level on the R4B to match that same level.

Worked good here...

Subject: [DrakeRadio] SPOT volume TOO LOUD!

I am using my R4A/T4XB in "separates" mode, have the FUNCTION switch on the R4A to external mute, and use the SPOT position on the T4XB so my TX frequency matches my RX frequency. That is all fine, but when chasing weak DX my GAIN controls on RX are pretty high, and when I go to SPOT to bring the TX VFO to my listening frequency the volume of the TX oscillator nearly blows my head off! Of course I can turn down RF or AF gain so this does not happen (and then when I am on frequency turn them back up again), but what a pain.

This is NOT the same as the sidetone volume. Is there some way to decrease the intensity of the SPOT signal (other than move the TX farther away from my RX)?

21283. Re: [DrakeRadio] R-4B receive??

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-31 03:08:41 UTC
From: David Nichols
Topic: 21260 Message: 21283

Ok now!
I just might have this figured out now. To start with I have been seeing instructions that wasnt there!
Where it says to Place The PASSBAND SELECTOR lever to .4????? MY Minds Eye saw the 4 and just put the lever on 4.8.. Let me tell you, you can not do the task with the lever in that position. Its actually not so hard to do if you place it in the point four position.

The other thing I figured out today is with the four slugs on the back of the passband tuner.

It is possible to have the highest negative voltage and not hear anything! I figured out that I had to keep turning the slug even after I reached the high reading in order to get some sound. Each slug is able to stay at the high voltage setting and also bring in the sound. I have this nice split alignment tool so I felt at ease playing with the little springs.

I still have a little doubt about the center screw adjustment but it is sounding good this evening.

Subject: Re: [DrakeRadio] R-4B receive??

David -

Well, I've never had an IFR, so can't help there. You mention tracking generator, so it may perform as a spectrum analyzer and would be good.

Ideally what you want to do is to scan a signal across the bandwidth of the tracking filter.
Easiest would be a signal that would sweep from say 5.640 to 5.650 MHz, along with a 'receiver'
that is scanning 45 to 55 kHz in 'sync'. Ideally, that receiver output would be applied to a
scope screen to register signal strength vs amplitude. The resultant 'picture' should look something like the filter passband picture on page 22 of the manual. As you adjust the Passband
tuner, the size, shape and position of that plot will change, and you just continue adjusting
for that picture.

The Noise bridge and AF spectrum analyzer method works in a similar fashion, except the noise
bridge puts a 'white' noise into the front end, which is essentially 'filling' the receiver passband with a constant 'hiss' across all frequencies. This 'flat' noise signal is shaped by
the filter passband(s) and is output is therefore shaped like the passband. The 'analyzer', something like 'Spectrascan' software or similar can display this shape on the PC screen.

I 'think' the IFR can do something to accomplish this task, but I have no idea how to do it.
Perhaps someone on the list can help??

I'm working on a project called the 'Poor Ham's Simple Network Analyzer'. It uses a couple of
Chinese modules to build a 1-30 MHz signal generator that can be swept over any specified range,
and an RF detector with a logarithmic output covering a range from +10 to -80 dBM. It works great for scanning a crystal filter and making a list of amplitude vs frequency that can be plotted using Excel or other similar program. The other part is a 'Network Analyzer Terminal'
which is a device that uses a display like a cellphone that controls the PHSNA and plots the
output on screen. Currently it can make a scan for each press of a space bar, which takes about
a second, but software is still under development to make it capable of scanning continuously,
like a spectrum analyzer. PC boards are available for the PHSNA, (less than $100 total cost),
and a kit is available for the NAT for $65. More info at the 'PHSNA' Yahoo group.

Garey,

Just saw the results of your work. Impressive, and more than adequate for I.F. filter alignment purposes. Are you using plotting software with the PHSNA to create the X-Y scales? Looks like the - 6dB points are roughly 600Hz and very close to the expected 500 Hz bandwidth!

Paul, W9AC

I actually saw this in your posts and MISSED it so you
are not the only one who can get numbers wrong.
If it helps any the pass band tuner is a four section
filter with variable _coupling_ to give it variable
bandwidth. When set up at the narrowest bandwidth the four
adjustments are pretty much independent of each other but
when expanded to maximum they interact. So, its tuned at
minimum bandwidth. You have discovered what happens when
its at maximum bandwidth.
This is a very clever devise. The first commercial
receiver with a tunable passband was the Collins 75A4. It
had a mechanical filter and changed bandwidth by having
three different filters on a switch. Beause the filter

frequency could not be changed the tuning had to be done indirectly by adjusing both the BFO and the main tuning together. This requires a complicated mechanical coupling. Drake accomplishes the same thing with fixed main and BFO tuning by making the filter itself tunable. The filter does not have quite the steep selectivity of a mechanical filter but its very good. In order to duplicate the selectivity of a mechanical filter more tunable coils (and maybe some tunable caps too) would be needed and it would become impractical.
I use alligator clips to adjust the slugs. This may not be to everyone's taste but I find it works well. I can grip the very tip of the slug wire and turn it then let it go without backlash. I also found that if the sound is too far different in the two sideband positions I can sometimes get them better by very carefully peaking the coils again at 400 hz bandwidth. It will _never_ be quite the same because the pass band is not quite symmetrical. Have a look at the graph in the handook. The expansion is also not symmetrical because of the type of coupling between tuned circuits, this also is apparent from the graphs and is the reason the range lines on the panel are not symmetrical. You will find a similar effect in the variable bandwidth IF filters in some Hallicrafters receivers. While the filter in the R4B may not be as steep as a mechanical or crystal filter its better than the filters in many conventional receivers. In combination with the notch filter, which works very well, its possible to tune out most QRM. BTW, the filter can be used for SSB in the 1.5 khz position too which may help when things get crowded. It may not sound great but you will be able to separate stations. The pass band tuning can also be used to push QRM off the edge of the filter. Between the PBT and the notch filter you can pull most stations out of the mush.

Garey,

OK, here is an update after staying away for a while: TR4 power supply lost HV. Bad filter cap. Used ps from T4X (which works fine with T4X), blew fuse. Found bad 6JB6 (filament short) in TR4 which caused T4X ps to pop fuses. Replaced 6JB6, and TR4 xmtr back working; still no rcvr. Can here 9 mHz and 21.5 mHz. Didn't listen for the 16 mHz mixer, though. Tube resistance cks good so far. My TR4 has a 6HS6 for V4, vs:6EV7, but chassis stamped 6HS6. V and R charts don't jive! Must be one of the TR4's caught in transistion? I will order the CD for the TR4. In the meantime, looking for more suggestions. Thanks

Jim, K5EH

21288. TR-4C - Need help finding that "Dip"!

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-31 10:41:19 UTC
From: Steve VK2SJA
Topic: 21260 Message: 21288

Hi Garey et-al,

Well I admit it. I'm confounded and confused.

I performed the PA Neutralization on my TR-4C using the Cold Screen method and a home brew W7ZOI RF power meter based on a AD8307 chip (I got the circuit from http://www.qrp.pops.net).

I seem to remember getting minimum Neutralization dip at about -70dBm (but tonight I can't find this written down in my lab-notebook. Grrr. I hate it when I forget to write important stuff down). Anyway the whole Neutralization process seemed to go "by the book" and worked very well. Or so I thought.

Now I have had the radio on-air with good signal reports. The art of tuning for max-smoke has been mastered. Doing this is easy enough and the radio makes plenty of power now all bands. But I kept reading "Dip the plate"!!! So I thought it best that I verify that my max-smoke did in fact equal minimum plate current.

Problem.

I have one of those really bad bouncy plate meters. I had placed a 47uF electro across it. This did tame the wild swings somewhat. But try as hard as I might I couldn't convince myself I was seeing a nice dip with max power out. In fact I found it hard to find any dip at all! I actually concluded that while the capacitor might tame the meter somewhat. That it may also be hiding a sharp and fast dip. And that I was tuning straight across it without seeing it.

So I went QRT for a couple of weekends and modified the radio to bring out the voltage sense for the plate meter to an external meter. Also built myself a FET-VM (since I didn't have a VTVM).

And I *still* can't easily find this illusive dip!

Here's what I seem to have on 40m tuning up into a dummy load:-

Tune for "max smoke" using external RF watt meter gets around 225+ watts at about 440mA plate current.

Adjusting the Plate control CCW from that point causes the plate current to start to rise. All good.

However adjusting the Plate control CW from that same point causes the plate current to drop. It continues to drop smoothly to a low of 395mA before it starts to rise again. Power out at that minimum point has dropped to about 135 watts.

So broadly speaking is this the "dip" I'm looking for (in which case it is quite broad) and if so then what have I done wrong re: Neutralization? And what should I do to fix it???

Other questions:

Is the plate current resonance "dip" I'm looking for very sharp or broad? By how much would it typically dip by?

I went back up to 29Mhz just for a quick sanity check and tried using the PA Neutralization procedure from the manual. I wasn?t doing the actual adjustment I was just seeing if I could swing the Plate control through resonance while the plate current was set to 200mA. Once again it seems that if I move CW from the "max smoke" position plate current starts to drop away but I found I couldn't find the bottom of the dip as the Plate control hit the stop before I found the bottom. Max smoke is very close to full CW.

Last question. How critical is the tune up of the final tank circuit for max smoke (resonance) *before* you adjust the PA Neutralization using the cold screen method? I did do this but I'm wondering if a tank control was carelessly bumped out of position while I was doing the adjustment.

Help... What should I try now?

73, Steve.

As you increase loading the dip will broaden out to the
point where its barely visible. This is normal and is a
characteristic of the tuned plate circuit. The sharpness of
the dip depends on the Q of the plate tank circuit, as the
load is increased, that is as the antenna load is coupled
more closely to the tank, the effective Q is lowered so the
resonance broadens out. At the peak load the plate tuning
will be more visible as a slight increase in power than as a
decrease in plate current but you should still check to be
sure the minimum plate current is still coincident with
maximum output. The Q of a parallel resonant circuit also
affects its resonant frequency a little which is why the
plate dip will change a bit as the load is increased. It
sounds like your TX is operating normally. The bouncing
meters are a PITA but the problem seems inherent in the
meter.

Jim -

OK. There are eight (8) versions of the TR-4, plus four (4) more of the TR-4C. All are on the
CD, which would be a big help in finding your way around the radio. Only version 1 used the 6HS6, all the rest used 6EJ7.

You should be able to hear the PTO, (4.9 to 5.5 MHz,) with 5.5 being 000 on the dial. 5.5 MHz
mixed with 21.5 should produce the 16 MHz in V3. That's the next target.

Don't put a whole lot of stock in the V-R charts. They didn't always change with the schematic. If a reading of V is within 20%, I wouldn't consider it a problem, and if more than
that, take a look at the correct schematic and you'll probably see why! :-) The R readings are
even more 'iffy'. Even if they are taken with a tube type VTVM, they aren't great. With any other meter, they can be all over the map depending upon Ohmmeter voltage and polarity.

21291. Re: [DrakeRadio] TR-4C - Need help finding that "Dip"!

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-31 18:03:38 UTC
From: Garey Barrell
Topic: 21260 Message: 21291

Steve -

As Richard said, the dip becomes broader as the LOAD increases. But it should still be easily
seen. Your cap may indeed be 'slowing' the response of the meter, making it more difficult to
find. With or without the cap you need to move the PLATE control VERY slowly at the dip to be
sure you get right on it.

Properly neutralized, tuning either way out of the dip should cause the output power to do DOWN. The tank circuit "Q" is highest on 10M, giving the sharpest dip at resonance. It's easier to see if you don't load all the way to maximum output.

Are these 6JB6(A)s? What brand of PA tubes do you have? Are they the SAME brand? "Mixed" brand tubes can neutralize on one band and be off on another, and very occasionally tubes of the
SAME brand can neutralize differently on different bands.

EXTRA output power with plate current 'off resonance' (non neutralized) power is not always where you think it is!! You might be surprised to see the output spectra under those conditions.

225 Watts is MORE than the TR-4C can put out _cleanly_.!

From: jim lewis
Topic: 21189 Message: 21293

Garey,

I forgot to add: I can see the S meter deflect when I tune accross the 1kHz oscillator, but still no audio or signal indications on the S meter.

Jim, K5EH

Jim -

OK. There are eight (8) versions of the TR-4, plus four (4) more of the TR-4C. All are on the
CD, which would be a big help in finding your way around the radio. Only version 1 used the 6HS6, all the rest used 6EJ7.

You should be able to hear the PTO, (4.9 to 5.5 MHz,) with 5.5 being 000 on the dial. 5.5 MHz
mixed with 21.5 should produce the 16 MHz in V3. That's the next target.

Don't put a whole lot of stock in the V-R charts. They didn't always change with the schematic. If a reading of V is within 20%, I wouldn't consider it a problem, and if more than
that, take a look at the correct schematic and you'll probably see why! :-) The R readings are
even more 'iffy'. Even if they are taken with a tube type VTVM, they aren't great. With any other meter, they can be all over the map depending upon Ohmmeter voltage and polarity.

73, Garey - K4OAH
Glen Allen, VA

Found bad 6JB6 (filament short) in TR4 which caused T4X ps to pop fuses. Replaced 6JB6, and TR4 xmtr back working; still no rcvr. Can here 9 mHz and 21.5 mHz. Didn't listen for the 16 mHz mixer, though. Tube resistance cks good so far. My TR4 has a 6HS6 for V4, vs:6EV7, but chassis

stamped 6HS6. V and R charts don't jive! Must be one of the TR4's caught in transistion? I will order the CD for the TR4. In the meantime, looking for more suggestions. Thanks

Garey,

No hiss with AF gain full CW; transmit OK; S meter deflects when tuning across 100 kHz Calibrator (misspoke b-4, said 1kHz); no signal indications on S mete, however.

voltage on pin 1, V19 is 250 vdc; pin 7 res. V3 = 2k, pin 7 on V7, V11, V12 = 100 ohms or less.

73, Jim, K5EH

From: Garey Barrell
Topic: 21189 Message: 21296

Jim -

OK. Are you comfortable around high voltage???

We're not going to intentionally get near it, but HV IS all over that radio.

What I would like you to do is to turn the AF GAIN control to about mid-range. Then touch a screwdriver blade to the center terminal of the AF GAIN pot while holding the insulated handle.
Once you're sure it's on the right spot, lightly touch your finger to the metal blade. You should get a LOUD hum. If you do, the problem is before the AF stage. If NOT, then the problem
is in the V17 stage.

There is NO HV in this area, just be sure what you are touching and don't slip off the terminal.

Report back!

73, Garey - K4OAH

Jim -

OK, bad audio stage. Only one tube, how hard can it be!! :-)

Pin voltages on V17. Pins 2, 7 5, 6.

73, Garey - K4OAH
Glen Allen, VA

Drake 2-B, 2-C/2-NT, 4-A, 4-B, C-Line
and TR-4/C Service Supplement CDs

Found bad 6JB6 (filament short) in TR4 which caused T4X ps to pop fuses. Replaced 6JB6, and TR4 xmtr back working; still no rcvr. Can here 9 mHz and 21.5 mHz. Didn't listen for the 16 mHz mixer, though. Tube resistance cks good so far. My TR4 has a 6HS6 for V4, vs:6EV7, but chassis stamped 6HS6. V and R charts don't jive! Must be one of the TR4's caught in transistion? I will order the CD for the TR4. In the meantime, looking for more suggestions. Thanks

21301. Re: [DrakeRadio] R-4B receive??

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-31 21:39:30 UTC
From: David Nichols
Topic: 21260 Message: 21301

Hi Richard,
I never thought about the alligator clip. I did try my small needle nose pliers but they where a miserable failure. Then I searched through my alignment tools and found the split one. It works great, by split I mean it has a small groove at the end instead of a screwdriver blade. Im happy they move with ease, that way I dont get any spring action I have to deal with.

These rigs can be pretty tricky for someone who cut their teeth on 12 volt solid state. While I grew up with tube radio and tv I never worked on any. hi hi

I love having something I can tinker with and then play with when Im done. I just wish I wouldnt blow things up. I seem to be good at that.

Subject: Re: [DrakeRadio] R-4B receive??

Ok now!
I just might have this figured out now. To start with I have
been seeing instructions that wasnt there!
Where it says to Place The PASSBAND SELECTOR lever to
.4????? MY Minds Eye saw the 4 and just put the lever on
4.8.. Let me tell you, you can not do the task with the
lever in that position. Its actually not so hard to do if
you place it in the point four position.

The other thing I figured out today is with the four slugs
on the back of the passband tuner.

It is possible to have the highest negative voltage and not
hear anything! I figured out that I had to keep turning the
slug even after I reached the high reading in order to get
some sound. Each slug is able to stay at the high voltage
setting and also bring in the sound. I have this nice split
alignment tool so I felt at ease playing with the little

springs.

I still have a little doubt about the center screw
adjustment but it is sounding good this evening.

David Nichols
KX7C - Addy, WA

I actually saw this in your posts and MISSED it so you
are not the only one who can get numbers wrong.
If it helps any the pass band tuner is a four section
filter with variable _coupling_ to give it variable
bandwidth. When set up at the narrowest bandwidth the four
adjustments are pretty much independent of each other but
when expanded to maximum they interact. So, its tuned at
minimum bandwidth. You have discovered what happens when
its at maximum bandwidth.
This is a very clever devise. The first commercial
receiver with a tunable passband was the Collins 75A4. It
had a mechanical filter and changed bandwidth by having
three different filters on a switch. Beause the filter
frequency could not be changed the tuning had to be done
indirectly by adjusing both the BFO and the main tuning
together. This requires a complicated mechanical coupling.
Drake accomplishes the same thing with fixed main and BFO
tuning by making the filter itself tunable. The filter does
not have quite the steep selectivity of a mechanical filter
but its very good. In order to duplicate the selectivity of
a mechanical filter more tunable coils (and maybe some
tunable caps too) would be needed and it would become
impractical.
I use alligator clips to adjust the slugs. This may
not be to everyone's taste but I find it works well. I can
grip the very tip of the slug wire and turn it then let it
go without backlash. I also found that if the sound is too
far different in the two sideband positions I can sometimes
get them better by very carefully peaking the coils again at
400 hz bandwidth. It will _never_ be quite the same because
the pass band is not quite symmetrical. Have a look at the
graph in the handook. The expansion is also not symmetrical
because of the type of coupling between tuned circuits, this
also is apparent from the graphs and is the reason the range
lines on the panel are not symmetrical. You will find a
similar effect in the variable bandwidth IF filters in some
Hallicrafters receivers. While the filter in the R4B may
not be as steep as a mechanical or crystal filter its better
than the filters in many conventional receivers. In
combination with the notch filter, which works very well,
its possible to tune out most QRM. BTW, the filter can be
used for SSB in the 1.5 khz position too which may help when
things get crowded. It may not sound great but you will be

able to separate stations. The pass band tuning can also
be used to push QRM off the edge of the filter. Between the
PBT and the notch filter you can pull most stations out of
the mush.

Paul -

The 'NAT' terminal plots them on the small screen immediately, but the data is captured in Excel
format so it goes directly into Excel if you want to print, pretty up, etc. Repetitive sweeps
are about 2 seconds apart, so not 'real time' but sure a lot better than tuning from end to end!! :-) You can also scan by pressing the SPACE bar.

The basic PHSNA is UNO based and puts out about 0 dBm from 1 - 30 MHz, or 1 - 60 MHz depending
upon plug-in module choice (AD9850 or 9851,) and can be run from a serial terminal. The 'fancy'
stuff is done with the NAT terminal about 3 x 5 'hand-held', from 'Midnight Science Solutions',
George, N2APB. There is also a Windows based controller program, but I haven't tried that yet. Lots of software development going on, I just got v2 of the NAT software which adds touch
screen control. v1 uses an ASCII keyboard with a PS-2 connector. and is all menu / keypress.

Well less than $100 for the PHSNA, and $65 for the NAT kit, + $8 for an enclosure, optional.
I've been working with the PHSNA since about last October, and it's really coming together.

There is also a 'receiver' project under way which will come very close to a spectrum analyzer.

21303. 6HS6 Tube?

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-05-31 22:02:55 UTC
From: n1ohn@yahoo.com
Topic: 21303 Message: 21303

Hello all :)

Well why looking on the bay for them 6HS6 tubes for my T-4XB and R-4B I noticed that one person has a GE 6HS6 Fisher tube? I never noticed a GE/ Fisher combination before what's the correlation with Fisher and GE?

Another thing that I was thinking of that I never thought of before is the tube ratings well a tube is tested say at 3000 to be NOS and say the tube test well over the NOS at 3400 is it possible that tube may actually fail for running let's say to hot?

I know that NOS ratings and tube testers are relative at best :)

Thanks
Dave :)

Garey,
Thanks for the hint on the location of the resistors. Disconnecting the shielded cable from T14. The voltage shifts correctly with the gain control.

Looking deeper I found the pin on T14 that the voltage is applied to was a direct short to ground. Looking into T14 I found D7 and D8 dead shorted.

That would explain a lot of things, as it also shorted the signal to ground at that point. It also explains why Am and SSB don't work either!). I will look for some replacement diodes, (I have a lot of small parts around).

As I stated before this was a basket case parts radio. So I expect to find more issues like this.

Having fun. This is the part of ham radio I really enjoy the most.

Thanks for the help.

Yeah, I saw that. You never know, 'there's one born every minute!' :-)

Personally, I would say 'worthless' rather than 'relative'. You can tell 'almost as much' with
an ohmmeter, or getting your finger close to it in circuit. "A" tube tester can be fairly consistent from tube to tube, but absolute values are iffy at best. A receiving tube that gets
hot will 'almost' certainly work well enough to 'play' in most circuits. RF is a little tougher, but not much. Yes, they can be destroyed and still get hot, but not all that likely.

Tube testers test at 60 Hz for the most part, so only a basic idea if most of the elements are
there. 'Emission' type testers tie all the grids together and to the cathode and measure how
the tube works as a rectifier at 60 Hz.

Check with Stan at ESRC1vacuumtubes.com.

Garey,

Pin voltages on V17 as follows:

pin 2 = 7.7vdc
pin 5 = 250 vdc
pin 6 = 150 vdc
pin 7 = 0

right in accordance with chart.

Jim, K5EH

Found bad 6JB6 (filament short) in TR4 which caused T4X ps to pop fuses. Replaced 6JB6, and TR4 xmtr back working; still no rcvr. Can here 9 mHz and 21.5 mHz. Didn't listen for the 16 mHz mixer, though. Tube resistance cks good so far. My TR4 has a 6HS6 for V4, vs:6EV7, but chassis stamped 6HS6. V and R charts don't jive! Must be one of the TR4's caught in transistion? I will order the CD for the TR4. In the meantime, looking for more suggestions. Thanks
